6 **Abstract**

7 This paper is about the proof of P ? NP based on the limiting factor that hinders the proof of  
8 P = NP when we consider randomness in the subset sum problem algorithm presented in this  
9 paper. Randomness in this paper is referred to an act of inputting integers to the program  
10 without pattern. The paper is not about to show case the extent in which the subset problem  
11 could be solved but to prove that P = NP does not exist in polynomial time. Literally,  
12 polynomial time means that as the complexity of the problem grows, the difficulty in solving it  
13 doesn't grow too fast. The proof of  $x \pm y = b$  at system 1 is the premise that was used in this  
14 paper to prove that P ? NP. The proof of  $x \pm y = b$  systems are forms of  $x \pm y = b$  that was  
15 derived from the coexistence of three quantities denoted by  $n, n + 1, n + 2$  where  $n$  represents  
16 any positive integer. See the proof of  $x \pm y = b$  at references for details. The proof of  $x \pm y =$   
17  $b$  at system 1 is the proof of a mathematical method that proves something can evolve from  
18 nothing and its graph shows that the shape of the universe is a cone and this can further be  
19 mapped with an expanding universe or universes to locate the point of the big bang (a  
20 hypothetical point in space where the universe began). See No.4, at references for details.

22 **Index terms**— input, systems, subset sum problem, algorithm, p ? np, the proof of  $x \pm y = b$ .

23 **1 I.**

24 Subset Sum Problem consider the subset sum problem, an example of a problem that is easy to verify, but whose  
25 answer may be difficult to compute. Given a set of integers, does some nonempty subset of them sum to 0? For  
26 instance, does a subset of the set  $\{-2, -3, 15, 14, 7, -10\}$  add up to 0? The answer "yes, because  $\{-2, -3, -10, 15\}$   
27 adds up to zero" can be quickly verified with three additions.

28 There is no known algorithm to find a subset that sum to 0 in polynomial time. Thus it takes a very long time  
29 to find a subset that sum to 0 as the complexity of the problem grows on a deterministic Turing machine given  
30 the computer's present state and any inputs (there is only one possible action that the computer might take) and  
31 sequential (it performs actions one after the other). Literally, polynomial time means that as the complexity of  
32 the problem grows, the difficulty in solving it doesn't grow too fast. Therefore, if there is a known algorithm to  
33 find a subset that sum to 0 in polynomial time then P = NP but if there is no known algorithm to find a subset  
34 that sum to 0 in polynomial time and it can be proved then P ? NP.

35 **2 II.**

36 **3 Premise**

37 Computers are deterministic and they cannot identify subset that sum to 0 or subset that do not sum Author:  
38 e-mail: alabikmartins@gmail.com to 0 without cause (a thing that makes something happen). It can be observed  
39 that there is no other information given to the computer rather than the input themselves. Therefore, for us to  
40 have a solution to the P vs NP problem the input must equate to something that is provable. Otherwise, the  
41 input is meaningless.

42 The proof of  $x \pm y = b$  at system 1 is the premise that was used in this paper to prove that P ? NP where  
 43 b is the total sum of input. The proof of  $x \pm y = b$  at system 1 gives a solution when integers that sum to 0  
 44 combines with one or two integers that do not sum to 0 regardless of input size.

#### 45 4 III.

#### 46 5 Assertion

47 If P = NP. Then a determinant would be found in polynomial time.

48 Determinant (a factor that causes something) here is referring to an integer n that gives indication or hint  
 49 about a subset that sum to 0 when the proof of  $x \pm y = b$  at system 1 is established in the subset sum problem.  
 50 They can be classified as a cause for subset that sum to the total sum of input.

51 Given that  $x \pm y = b$  where b is the solution to any given number x and y for which x is number i or j.

52 So that,  $i + y = b$ . Also that,  $j - y = b$ . Let  $i = (nb + n) / n + 1$ . Let  $y = (b - n) / n + 1$ . Let  $j = (nb + 2b$   
 53  $-n) / n + 1$ .

54 Therefore the proof of  $x \pm y = b$  system is given as:  $(nb + n) / n + 1 + (b - n) / n + 1 = b$ .  $(nb + 2b - n) / n$   
 55  $+ 1 - (b - n) / n + 1 = b$ .

56 System 'n' is a system which  $x \pm y = b$  belongs for every given positive integer n. For instance, when n =  
 57 1. Let  $i = (b + n) / 2$ . Let  $y = (b - n) / 2$ . Let  $j = (3b - n) / 2$ .

58 Therefore the proof of  $x \pm y = b$  at system 1 is given as:  $(b + n) / 2 + (b - n) / 2 = b$ .  $(3b - n) / 2 - (b - n) / 2$   
 59  $= b$ .

#### 60 6 C

61 Abstract-The proof of  $x \pm y = b$  at system 1 is the premise that was used to prove that P ? NP where b is the  
 62 total sum of input in the subset sum problem. The proof of  $x \pm y = b$  systems are forms of  $x \pm y = b$  that  
 63 was derived from the coexistence of three quantities denoted by n, n + 1, n + 2 where n represents any positive  
 64 integer. The proof of  $x \pm y = b$  at system 1 is a computable function definable by an algorithm where n is  
 65 the argument (input value) of the function to the corresponding output value b. System 1 can be defined as a  
 66 system which the proof of  $x \pm y = b$  belongs when n = 1. The proof of  $x \pm y = b$  at system 1 is the proof of a  
 67 mathematical method that proves something can evolve from nothing and its graph shows that the shape of the  
 68 universe is a cone and this can further be mapped with an expanding universe or universes to locate the point of  
 69 the big bang .i.e. a hypothetical point in space where the universe began. See the reference list for details.

#### 70 7 Search for Determinant

71 Given a set of integers  $\{-2, -3, 15, 14, 7, -10\}$  does some nonempty subset of them sum to 0? Let i denote each  
 72 integer in the set.

73 Since input  $\{-2, -3, 15, 14, 7, -10\}$  equals 21. Then b = 21.

74 The proof of  $x \pm y = b$  at system 1 is implicit. When we know i and b we can know n by making use of the  
 75 formula  $n = (2 \times i) - b$  derived from the proof of  $x \pm y = b$  at system 1. For i = -2, n = -25.

76 For i = 15, n = 9. For i = 14, n = 7. For i = 7, n = -7.

77 For i = -3, n = -31. For i = -10, n = -41. i = 14 when n = 7 and i = 7 when n = -7.

78 Since  $7 + (-7) = 0$ . Then n = 7 is a determinant and n = -7 is a determinant.

79 First hint: If the sum of equal and opposite values for n equals 0 outputs all integers in the set except integers  
 80 that reference equal and opposite values for n. Therefore the answer is subset  $\{-2, -3, 15, -10\}$  which adds up to  
 81 zero.

82 Given a set of integers  $\{-2, -3, 15, 14, -10\}$  does some nonempty subset of them sum to 0? Let i denote each  
 83 integer in the set.

84 Since input  $\{-2, -3, 15, 14, 7, -10\}$  equals 14. Then b = 14. By using the formula  $n = (2 \times i) - b$  derived from  
 85 the proof of  $x \pm y = b$  at system 1. For i = -2, n = -18. For i = -3, n = -20.

86 For i = 15, n = 16. For i = 14, n = 14.

87 For i = -10, n = -34. i = 14 when n = 14. Since n = 14. Then 14 is a determinant.

88 Second hint: If n is equal to the total sum of input output all integers in the set except the integer that has  
 89 equal value with the total sum of input. Therefore the answer is subset  $\{-2, -3, 15, -10\}$  which adds up to zero.

90 V.

#### 91 8 Complexity

92 The complexity of the problem grows as we increase the length of random input. For instance, given a set of  
 93 integers  $\{-2, -3, 15, 14, 7, -10, 50\}$  does some nonempty subset of them sum to 0? Let i denote each integer in  
 94 the set.

95 Since input  $\{-2, -3, 15, 14, 7, -10, 50\}$  equals 71. Then b = 71.

96 By using the formula  $n = (2 \times i) - b$  derived from the proof of  $x \pm y = b$  at system 1.

97 For i = -2, n = -75. For i = -3, n = -77.

98 For i = 15, n = -41. For i = 14, n = -43. For i = 7, n = -57.

---

99 For  $i = -10$ ,  $n = -91$ . For  $i = 50$ ,  $n = 29$ .  
100 No answer could be found because of absence of a determinant. Therefore no hint is applicable.

101 **9 a) Comment**

102 The algorithm presented in this paper outputs subset that sum to 0 quickly if we enter integers that sum to 0  
103 as many as possible with one or two integers that do not sum to 0 via the program below e. Is  $P = NP$ ? This is  
104 the real question we are concerned with. Is the set of problems in  $P$  actually the same as the set of problems in  
105  $NP$ ? The program is a  $P$  algorithm; an answer in polynomial time is called  $P$ . Questions for which an answer can  
106 be verified in Thus it is concluded that the existence of an algorithm exists in polynomial time ( $P$ ) only if the  
107 algorithm runs in polynomial time regardless of input size. ? Here's a  $P$  program that does solve the problem ?  
108 It does solve the problem because the problem does not exist in  $P$ .  
109 ? Therefore  $P ? NP$ .  
110 polynomial time is called  $NP$ . The program terminates and those  $NP$ -complete problems do not exist in  $P$   
therefore,  $P ? NP$ .<sup>1</sup>

112 .1 Conclusion

113 Subset sum problem is NP-complete and the proof of  $x \pm y = b$  at system 1 has been established in the subset  
114 sum problem and each number is equally probable. This justifies that each integer in the set of integers are in  
115 conjunction with 'b'. Therefore, the algorithm and the assertion presented in this paper can be dependent on as  
116 reliable.

117 The program outputs subset that sum to 0 quickly when integers that sum to 0 combines with one or two  
118 integers that do not sum to 0 regardless of input size. As the complexity of the problem grows the program  
119 terminates quickly without an answer.
