4

In this article, we present the multichannel architecture of the analog-to-digital converter 7 based on the duty cycle modulation technique with prototyping on FPGA hardware targets. 8 This diagram is the continuation of the work presented in [1],[2] proving the feasibility of the 9 single-channel version of this converter on the one hand and its characterization on the other. 10 This conversion approach is based on the use of parallel duty cycle modulation cells, each used 11 as an independent 1-bit interfacing circuit per analog channel. In addition, all of the 12 modulated output bits associated with all of the analog inputs are simultaneously sampled 13 and processed. The principle already demonstrated [11] and the important properties revealed 14 by this A / D conversion scheme studied in depth in the review articles are presented, then, an 15 experiment with a 4-channel virtual oscilloscope is presented, in order to show the potential 16 results of the prototype of the multi-channel version of the FPGA-based converter. The design 17 and implementation are carried out by software and hardware co-simulation using platforms 18 such as the Simulink / Xilinx based system generators in which the ODCM-ADC is 19 implemented, and the programming tool Vivado 2019.2 from Xilinx. The hardware platform 20 consists of the Zynq 7000 FPGA kit (25 MHz sample clock), equipped with an integrated 21 FPGA-based IIR (infinite impulse response) digital decimation filter and a JTAG 22 communication cable / connectors on PC. The co-simulation systems are built and 23 successfully tested for a modulating bandwidth of 3 KHz. These performance levels, obtained 24 under virtual and hardware co-simulation conditions, show a relevant challenge of an 25 oversampling multichannel ADC, compared to most ADC oversampling techniques. As a 26 merit, the proposed FPGA-based ADC technique is a novel and relevant ADC architecture for 27 on-board instrumentation systems and industrial electronics. 28

29

³² 1 INTRODUCTION

33 ultichannel analog-to-digital converters (ADCs) are necessary in a context of digital processing of signals coming 34 from several sensors or sources given that nature is essentially analog through its manifestations which can 35 be images, sound, vibrations. The great power of digital computers has revolutionized the fields of industrial 36 instrumentation and systems engineering through analog-to-digital converters which combine the role of interface between the analog world and the computer. Many applications require the digitization of signals from current 37 output sensors, such as photo sensors and photodiodes, and in multichannel conversion systems lower power per 38 channel is important so that as the number of channels increases, the power does not increase. not increase 39 drastically [3], [4]. Thus, the possibility of directly digitizing the currents without current-to-voltage conversion 40 saves the energy, the surface area and the design time necessary for the implementation of the converters. The 41 main objective of this article is to study and implement on FPGA and test an optimal multichannel cyclic 42

 communication.

cycle modulation ADC. This circuit provides an interface to analog sensors and minimizes the dynamic range
 dependence of the conventional oversampling ADC on the supply voltage. The following sections explain the
 history, background, of the duty cycle modulation technique.

Fig. ??: Oversampling ADC principle [1] In Section II, the knowledge on the DCM-based ADC topology is 46 outlined. Then, a case study and prototyping multi-channel A/D converter is presented in Section III, followed in 47 Section IV by the hadware cosimulation results. Then, the conclusion of the paper is presented in Section V. The 48 block diagram of our multi-channel ODCM-ADC is inspired by the single-channel converter taken from [2], and 49 is shown in Fig. ??. It consists of two main parts, connected in tandem, that is to say an optimal upstream DCM 50 circuit (see Fig. 2 (a)) with modulating input x and DCM output xm (t), and an optimal downstream digital filter 51 IIR (Infinite Impulse Response) (see Fig. 2 (b)). The optimal DCM demodulator circuit is modeled by a set of 52 nonlinear parameters which form a constrained optimization problem, while the optimal IIR filter is synthesized 53 according to the specifications of the weighted pth standard. The optimal parameters of multichannel ADC 54 system prototyping based on optimal duty cycle modulation considered in this section are taken from previous 55 work [] namely: fs = 25MHz (sampling period or Ts = 1 / fs = 40 ns so equivalent), fs = 3KHz (modulating 56 bandwidth), fm (0) = 172 KHz (DCM base oversampling frequency), E = 9 volts (power), * = 0.012366816265686 57 58 where ? * = R1 / (R1 + R2) and RC = 0.000115510618677 s. It should be remembered from [1] that the DCM 59 circuit shown in Fig. 2 is modeled by equation (1), which is quite easy to implement in the Matlab / Simulink 60 framework. In addition, the transfer function z of the second-order optimal digital IIR decimation filter is given 61 by (2).

⁶⁷ 3 III. FPGA-BASED OF MULTI-CHANNEL ODCM-ADC ⁶⁸ DESIGN

⁶⁹ The FPGA-Based multichannel ODCM-ADC design is conducted under Simulink workspace, according to the ⁷⁰ schematic diagram presented in Fig. ??. The upstream subsystem shown in Fig. 3(c). As in the case of single ⁷¹ input ODCM or sigma-delta A/D converters ([1], [2]), an important problem to take into account when sampling ⁷² a discrete sequence given by "Eq. 3", is the over sampling phenomenon [10] It is due to the fact that the analog ⁷³ original version of "Eq. 3" is a time varying square wave, with a wider bandwidth compared to that of the ⁷⁴ modulating wavex(t) encapsulated in R m (x(t)). (2R m (x, ?) ? 1)E + 4E ? ? sin ? n ? R m (x,?) n ? cos 2? ⁷⁵ n t T m (x) ? n=1

Thus, the sampling theorem used in digital signal processing [1], is applicable in this case to the target 76 modulated wave x m (t) to be sampled. Let fosc (x j t))(being the fundamental frequency of the oscillator 77 associated with the jth channel, its maximum value fosc max which occurs for $x_j(t) = 0$, is assumed to be an 78 identical constant for all channels, in which case the bandwidth f max related to the periodic square wave is 79 large enough compared to f max [9]. Thus, assuming that the admissible bandwidth of the jth analog signal 80 $x_j(t)$ is a constant fBj, then the following constraint should be satisfied when choosing the simultaneous sampling 81 frequency fs ,? ? ? ? ? δ ??" δ ??" ?????? (0, ?) = 1 2.??.ln ? ?? +1 1??? 1 ? δ ??" δ ??" ?????? (x max, ?) = 82 1 ??.ln (?((1???) x max) 2 ?((?? +1)??) 2 ? ?((1???) x max) 2 ?((?? ?1)??) 2 ? (4) 83

Fig. 3(a) is a Simulink-based model of the DCM circuit given by (1), with analog modulating input Xs? x 84 as in Fig. 2(a), and with a sampled modulation output xm. Then, the downstream subsystem presented in Fig. 85 2(b) is modelled as a digital IIR filter given by (2), which is implemented using visual building resources and 86 configuration panels available in Xilinx System generator frame work. The IIR filter is implemented according to 87 the direct form approach. The implemented only required 5 multipliers, 5 registers and an added tree, although 88 the full resolution is maintained across the multipliers and the tree. In addition, the data width cannot grow 89 indefinitely, and thus a quantization block is placed at the output of the adder to reduce the width of the data. At 90 this step, it is worth noting that the whole schematic diagrams presented in Fig 2, is tested over the modulating 91 band width followed by the creation and the configuration of an additional hwcosimblock for further hardware 92 co-simulation requirements. In addition, the DSP code for the target FPGA is generated as an input module for 93 XilinxISE framework. As an implication the related high level RTL diagram shown in Fig. ??, is organized into 94 9 digital processing modules. 95

⁹⁶ 4 a) Virtual Simulation of the multichannel ODCM-Based

ADC System Following (2), the ODCM-based ADC system, designed in depth in this section, has been implemented in Simulink framework as shown in the virtual model (see Fig. ??). It consists of a visual model of the optimal DCM block as shown in Fig. ?? (a), corresponding to the first order dynamic model(2), and a discrete transfer function F(z) of the optimal second order digital IIR filter.

⁶⁶

The simulation required for performance evaluation of the overall prototyping ODCM-based ADC, is conducted over a sufficiently wide range of frequency including the modulating bandwidth of 3 KHz. In addition, a sample of detailed result related to a sine modulating input (1 KHz, 100Hz, 1.5kHz, 2kHz, 1 Vpp) is presented in Fig. ??, whereas all results of hardware cosimulation obtained under variable modulating frequencies are summarized in Fig. ?? [5].

$_{106}$ 5 b) Design chart of a multichannel ODCM-ADC based on FPGA

The design workflow for an FPGA application is usually done in several stages. First of all, algorithmic specifications make it possible to define the architecture by an algorithm-architecture fit approach. This architecture is then described with the HDL language. You can then simulate the system and modify it if necessary [2]. Then come the phases of synthesis and routing placement, which consist in determining which elements will actually be used in the FPGA and how they will be connected to each other, where in the component they will be placed, etc. Each phase requires verification of the correct timing and, if necessary, modifications.

The hardware description language such as VHDL or Verilog, usually used for the development of FPGAs, are 114 of a concurrent nature. Programming in VHDL implies a good knowledge not only of the algorithm but also of 115 the FPGA and the compiler used [2]. To better exploit the intrinsic parallelism of the algorithm, it is necessary 116 to perform the processing tasks in parallel (non-sequential) to satisfy the time constraints. For most control or 117 signal processing specialists who are very often software researchers and engineers, these hardware languages are 118 unfamiliar and sometimes difficult to use. This is probably one of the reasons holding back the democratization 119 of FPGA technology. In an attempt to provide an appropriate solution to this problem, co-design platforms by 120 association of several development environments have been proposed. The general System Generator/Silulink 121 chart is schown in figure 3. 122

123 6 HARDWARE CO-SIMULATION OF MULTICHANNEL 124 ODCM-ADC

Co-design is the design technique of the day for its many advantages so one can co-use MATLAB / Simulink software and System Generator building blocks to implement SISO downlink chip systems. or to propose a design of QPSK modulator on FPGA which consumes little power and using the hardware cosimulation, to obtain a reduction in the cost of the hardware requirements.

As part of this work, the development of the converter prototype is carried out with the XSG software. This is a 129 130 toolkit developed by Xilinx to be integrated into the Matlab/Simulink environment and which lets the user create 131 highly parallel systems for FPGAs. The created models are displayed as blocks, and can be linked to other blocks 132 and to other Matlab-Simulink toolkits such as SPS. Once the system is complete, the VHDL code generated by the XSG tool exactly reproduces the behavior observed in Matlab. For rapid prototyping, the choice of this tool 133 is easily explained. As the conversion system needs to be checked and simulated often and quickly throughout 134 development, it is much easier to analyze the results with Matlab than with the tools usually associated with 135 VHDL, such as Modelsim [6], [7]. When the prototype is up and running, the switch to the hardware platform 136 for field testing is rapid, making validation of the prototype a feasible project in the short term. The PC and the 137 FPGA board are connected via a suitable communication cable/connectors (USB, Ethernet or JTAG). Thus, in 138 a hardware co-simulation context, the digital signals involved in a DSP/FPGA chip are automatically uploaded 139 to the PC-based virtual platform for real-time visualization. During a cosimulation session, the virtual simulator 140 and the hardware DSP are simultaneously started and driven under the same operating conditions (input and 141 parameters), while the real-time behavior of the hardware DSP is brought to the virtual simulation environment 142 for rapid design, visualization and performance evaluation [8]. The co-simulation environment created in this 143 research work for the rapid computation and evaluation of the predicted and experimental characteristics of multi-144 channel ODCM-ADC prototyping based on FPGA, is presented in Fig. ?? Figure ??: FPGA-Based ODCM-ADC 145 design architecture [2] Figure ??: Hardware Co-Simulation environment Finally, a summary of simulation results 146 obtained are presented in Fig. 7. 147

The results presented here show that, the proposed multichannel ODCM-based ADC offers high performance 148 within 3 KHz of modulating bandwidth. The high level of predicted performance obtained from virtual simulation 149 of a prototyping system, is a great challenge an oversampling ADC topology, consisting of a piece of ODCM circuit 150 with impressive properties, and a single stage of optimal 2 nd order digital decimation filter. The figure above 151 152 shows the converter model produced in Matlab's Simulink environment. The modulator is realized in Simulink 153 while the second order RII filter is realized together in simulink for virtual simulation. For the software co-154 simulation, the blocks of the Xilinx System Generator toolbox were used. A successful simulation in the System Generator environment generates the hardware co-design block that allows the Matlab/Simulinx environment 155 to interact with the Zynq 7000 board. The filter will be implemented using the 4x4Filter block from Xilinx. 156 The 4x4Filter block is a 4x4 mask that scans four lines of the input signal at a time to apply the chosen filter. 157 Therefore, the system requires a buffer that accepts four lines of inputs at a time to be fed into the filter. Figure 158 ?? is the model which shows how to design for the assembly. 159

161 8 CONCLUSION

This research was carried out in phases. First, the use of a filtering block with an input multiplexer and an output 162 demultiplexer was studied, then 4x4 filtering blocks were studied. A unique way has been identified to incorporate 163 these design techniques into the existing analog-to-digital converter so that the advantages of this mode of circuit 164 design can be used to overcome some existing problems in the multi-channel architecture. The applications of 165 this architecture are then defined. The sub-blocks of the architecture have been defined and designed according 166 to the required specifications. The design and co-simulation have been successfully implemented on the Xilinx 167 ZYNQ 7000 FPGA hardware target. It should be noted that the analog-to-digital converter thus produced based 168 owes its low cost of implementation and its high quality (stability, precision and robustness) both to the material 169 simplicity and to the topological relevance of its DCM circuit. interfacing. As a major discovery, the FPGA-based 170 multichannel ODCM-ADC presented in this article, could be used as a potential new architectural solution for 171 1 2 3 on-board instrumentation systems.
