7 Abstract

8 In a number of scientific publications is asserted that the permittivity and permeability of

⁹ material media depends on frequency. But even Maxwell himself, who was the author of the

¹⁰ basic equations of electrodynamics, believed that ? and ? were frequency-independent

¹¹ fundamental constants. The article shows that Max well was right, and the recognition of the

¹² presence of dispersion in the dielectric constant and magnetic permeability is a physical and

¹³ methodological error. In it is shown that the kinetic inductance of charge has the same

¹⁴ fundamental value as the dielectric and magnetic constant of material media. Are introduced

¹⁵ the new concepts of the magneto electro kinetic wave and electro magneto potential waves,

¹⁶ and also the kinetic capacitance.

20 1 Introduction

ow the idea of ? and u-dispersion appeared and evolved is illustrated vividly in the monograph of well-known 21 specialists in physics of plasma [1]: while working at the equations of electrodynamics of material, media, G. 22 Maxwell looked upon electric and magnetic inductivities as constants (that is why this approach was so lasting). 23 Much later, at the beginning of the XX century, G. Heavisidr and R.Wull put forward their explanation for 24 phenomena of optical dispersion (in particular rainbow) in which electric and magnetic inductivities came as 25 functions of frequency. Quite recently, in the mid-50ies of the last century, physicists arrived at the conclusion 26 27 that these parameters were dependent not only on the frequency but on the wave vector as well. That was a revolutionary breakaway from the current concepts. The importance of the problem is clearly illustrated by what 28 happened at a seminar held by L. D. Landau in 1954, where he interrupted A. L. Akhiezer reporting on the 29 subject: "Nonsense, the refractive index cannot be a function of the refractive index". Note, this was said by L. 30 D. Landau, an outstanding physicist of our time. 31 What is the actual situation? Running ahead, I can admit that Maxwell was right: both? and µ are frequency 32

-independent constants characterizing one or another material medium. Since dispersion of electric and magnetic
 inductivities of material media is one of the basic problems of the present -day physics and electrodynamics, the
 system of views on these questions has to be radically altered again.

36 **2** II.

37 **3** Plasma Media

It is noted in the introduction that dispersion of electric and magnetic inductivities of material media is a commonly accepted idea [1][2][3][4][5]. The idea is however not correct.

To explain this statement and to gain a better understanding of the physical essence of the problem, we start with a simple example showing how electric lumped-parameter circuits can be described [6]. As we can see

- below, this example is directly concerned with the problem of our interest and will give us a better insight into
 the physical picture of the electro dynamic processes in material media.
- In a parallel resonance circuit including a capacitor ? and an inductance coil L, the applied voltage U and the total current I ? through the circuit are related as? + = + = ? t d U L t d U d C I I I L C 1, where t d U d C I C = is the current through the capacitor, ? = t d U L I L 1

is the current through the inductance coil. For the harmonic voltage U = U 0 sin ?tt U L C I ? ? ? cos 1 0 ? 48 ? ? ? ? ? ? ? ? ? ? ? ? . (2.1)

The term in brackets is the total susceptance ? ? of the circuit, which consists of the capacitive ? ? and inductive ? L components From the mathematical (i.e. other than physical) standpoint, we may assume a circuit that has only a capacitor and no inductance coil. Its frequencydependent capacitance isL C L c x ? ? ? ? ? ? ? ? ? ? ? ?

that has only a capacitor and no inductance contribution requency dependent capacitant $_{52} = + = . H \odot 2014$ Global Journals Inc. (US)

⁵³ 4 Global Journal of Researches in Engineering

55 Another approach is possible, which is correct too.

In this case the circuit is assumed to include only an inductance coil and no capacitor. Its frequency dependent inductance is ?????????????????????

We shall not consider here any other cases, e.g., series or more complex circuits. It is however important to note that applying the above method, any circuit consisting of the reactive components C and L can be described either through frequency -dependent inductance or frequency -dependent capacitance.

62 But this is only a mathematical description of real circuits with constant -value reactive elements.

It is well known that the energy stored in the capacitor and inductance coil can be found as 2.1 U C W C =

64 , (2.6) 2 2 1 I L W L = . (2.7)

 65 But what can be done if we have) (* ? C and

$_{66}$ 5) (* ? L

67 ? There is no way of substituting them into Eqs.

(2.6) and (2.7) because they can be both positive and negative. It can be shown readily that the energy stored in the circuit analyzed is 2 2 1 U d d W X ??? ? = ?, (2.8)

Having written Eqs. (2.8), (2.9) or (2.10) in greater detail, we arrive at the same result:, 2 1 2 1 2 2 I L U C W + = ?

⁷³ Where U is the voltage at the capacitor and I is the current through the inductance coil. Below we consider ⁷⁴ the physical meaning jog the magnitudes ?(?) and $\mu(?)$ for material media.

A superconductor is a perfect plasma medium in which charge carriers (electrons) can move without friction. In this case the equation of motion is $E \in d V d m$? = , (2.11)

⁷⁷ Where m and e are the electron mass and charge, respectively; E ? is the electric field strength, V ? is the ⁷⁸ velocity. Taking into account the current density, V e n j ? ? = (2.12)

- we can obtain from Eq. (2.11)? = t d E m e n j L ? ? 2.
- 80

81 In Eqs. (2.12) and (2. ? = t d E L j k L ? ? 1. (2.14)

Here L k is the kinetic inductivity of the medium [7][8][9][10][11]. Its existence is based on the fact that a charge carrier has a mass and hence it possesses inertia properties.

For harmonic fields we have is the current through the inductance coil.t E E ? sin 0 ? ? = and Eq. (2.14) becomes t E L j k L ? ? cos 1 0 ? = ? . (2

In this case the Maxwell equations take the following form , 1 ,0 0 ? + = + = ? = t d E L t E j j H rot t H E rot k L C ? ? ? ? ? ? ? ? ? ? ? ? (2.16)

Where ? 0 and μ 0 are the electric and magnetic inductivities in vacuum, = + + H L t H H rot rot k ? ? ? μ ? ? ? μ .

For time-independent fields, Eq. (2.17) transforms into the London equation [12] $0 \ 0 = + H \ L \ H$ rot rot k? 92 ? μ , where 0 2 μ ? k L L =

93 is the London depth of penetration.

As Eq. (2.16) shows, the inductivities of plasma (both electric and magnetic) are frequencyindependent and equal to the corresponding parameters for vacuum. Besides, such plasma has another fundamental material characteristic -kinetic inductivity.

Eqs. (2.16) hold for both constant and variable fields. For harmonic fieldst E E ? sin 0 ? ? = , Eq.(2.16) gives t E L H rot k ? ? ? $\cos 1 0 0$? ? ? ? ? ? ? ? ? ? ? ? ? . (2.18)

101 ? = ? ? ? ? ? ? 2 0 1) (* , where k L 0 2 1 ? ? ? =

^{89 ? ? ?} μ.
90 (2.17)

- is the plasma frequency. Now Eq. (2.19) can be re-written ast E H rot ?????? cos 1 0 2 2 0 ?????? 103 ????? =, or t E H rot ???? cos) (*0?? =.
- 109 L k *(?) written this way includes both ? 0 and L k .
- Eqs. (2.20) and (2.21) are equivalent, and it is safe to say that plasma is characterized by the frequencydependent kinetic inductance L k *(?) rather than by the frequency-dependent electric inductivity ?*(?).
- Eq. (2.18) can be re-written using the parameters ?*(?) and L k *(?) Thus, the parameter ?*(?) is not an electric inductivity though it has its dimensions. The same can be said about L k *(?).t E H rot ? ? ? ? cos) (* 0 ? ? = , (2.22) or t E L H rot k ? ? ? cos) (* 1 0 ? ? = . (2)
- 115 We can see readily that? ? ? ? $X = (*, ??? X \ k \ L 1) (* = .$
- These relations describe the physical meaning of $?^{*}(?)$ and L k $^{*}(?)$.
- Of course, the parameters $?^{*}(?)$ and L k *(?) are hardly usable for calculating energy by the following equations 2 0 2 1 E W E ? = and 2 0 2 1 j L W k j = .
- For this purpose the Eq. (2.9)-type formula was devised in [2]:[] 2 0) (* 2 1 E d d W?????? = .
- 120 (2.24)

There is however another reason for this serious mistake in the present-day physics [2] as an example. This study states that there is no difference between dielectrics and conductors at very high frequencies. On this basis the authors suggest the existence of a polarization vector in conducting media and this vector is introduced from the relation m r e n r e P??? = ? = , (2.25)

Where n is the charge carrier density, m r? is the current charge displacement. This approach is physically 131 erroneous because only bound charges can polarize and form electric dipoles when the external field overcoming 132 the attraction force of the bound charges accumulates extra electrostatic energy in the dipoles. In conductors the 133 charges are not bound and their displacement would not produce any extra electrostatic energy. This is especially 134 obvious if we employ the induction technique to induce current (i.e. to displace charges) in a ring conductor. In 135 this case there is no restoring force to act upon the charges, hence, no electric polarization is possible. In [2] the 136 polarization vector found from Eq. (2.25) is introduced into the electric induction of conducting media E P E D 137 p????????????????=+=22001)(*)(*?????????138

139 Thus, the total accumulated energy is 2 2 2 0 1 2 1 2 1 E L E W k ? ? ? + = ? .

140 (2.26) However, the second term in the right-hand side of Eq. (2.26) is the kinetic energy (in contrast to 141 dielectrics for which this term is the potential energy).

Hence, the electric induction vector $D^*(?)$ does not correspond to the physical definition of the electric induction vector.

The physical meaning of the introduced vector) (*? P? is clear from E L E P k L???? 2 1) (*????? = 145 = .

The interpretation of ?(?) as frequencydependent inductivity has been harmful for correct understanding of the real physical picture (especially in the educational processes). Besides, it has drawn away the researchers attention from some physical phenomena in plasma, which first of all include the transverse plasma resonance and three energy components of the magneto electro kinetic wave propagating in plasma [13][14].

¹⁵⁰ **6 III.**

¹⁵¹ 7 Dielectric Media

Applied fields cause polarization of bound charges in dielectrics. The polarization takes some energy from the field source, and the dielectric accumulates extra electrostatic energy. The extent of displacement of the polarized charges from the equilibrium is dependent on the electric field and the coefficient of elasticity ?, characterizing the elasticity of the charge bonds. These parameters are related as). 1 () (* 2 0 2 2 0 ? ? ? ? ? ? ? ? ? ? ? ? ? It is appropriate to examine two limiting cases:?»? 0 and?«? 0. If ?»? 0 ,) 1 () (* 2 2 0 ? ? ? ? ? ? ? ? ? ? ? ? =

, and the dielectric behaves just like plasma. This case has prompted the idea that at high frequencies there is
no difference between dielectrics and plasma. The idea served as a basis for introducing the polarization vector
in conductors [2]. The difference however exists and it is of fundamental importance. In dielectrics, because of
inertia, the amplitude of charge vibrations is very small at high frequencies and so is the polarization vector. The

162 polarization vector is always zero in conductors.

163 For ?«? 0 , IV.

¹⁶⁴ 8 Magnetic Media

The resonance phenomena in plasma and dielectrics are characterized by repeated electrostatickinetic and kineticelectrostatic transformations of the charge motion energy during oscillations. This can be described as an electrokinetic process, and devices based on it (lasers, masers, filters, etc.) can be classified as electrokinetic units.

is the medium magnetization.

can be described as kinetic capacitance [16][17]. What is its physical meaning? If the direction of the magnetic moment does not coincide with that of the external magnetic field, the vector of the moment starts precessional motion at the frequency ? about the magnetic field vector. The magnetic moment m ? has the potential energyB m U m ? ? ? ? =

184 . Like in a charged condenser, U m is the potential energy because the precessional motion is inertia less (even 185 though it is mechanical) and it stops immediately when the magnetic field is lifted. In the magnetic field the 186 processional motion lasts until the accumulated potential energy is exhausted and the vector of the magnetic 187 moment becomes parallel to the vector 0 H?. Magnetic resonance occurs at the point ?=? and μ ? *(?)???. It 188 is seen that the resonance frequency of the macroscopic magnetic resonator is independent of the line size and 189 equals ?.

190 Thus, the parameter? ? ? ? ? ? ? ? ? ? ? ? = 2 2 2 0) 1 (1) (* ? $\mu \mu$? μ H

is not a frequency-dependent permeability.

192

¹⁹³ 9 Conclusion

Thus, it has been found that along with the fundamental parameters ?? 0 and µµ 0 characterizing the electric and 194 magnetic energy accumulated and transferred in the medium, there are two more basic material parameters L k 195 and C k. They characterize kinetic and potential energy that can be accumulated and transferred in material 196 media. L k was sometimes used to describe certain physical phenomena, for example, in super conductors, 197 C k has never been known to exist. These four fundamental parameters ?? 0, $\mu\mu 0$, L k and C k clarify 198 the physical picture of the wave and resonance processes in material media in applied electromagnetic fields. 199 Previously, only electromagnetic waves were thought to propagate and transfer energy in material media. It is 200 clear now that the concept was not complete. In fact, magneto electro kinetic, or electro magneto potential 201 waves travel in material media. The resonances in these media also have specific features. Unlike closed planes 202 with electromagnetic resonance and energy exchange between electric and magnetic fields, material media have 203 two types of resonanceelectro kinetic and magneto potential. Under the electro kinetic resonance the energy 204 of the electric field changes to kinetic energy. In the case of magneto potential resonance the potential energy 205 accumulated The notions of permittivity and permeability dispersion thus become physically groundless though 206 ? * (?) and μ * (?) are handy for a mathematical description of the processes in material media. We should 207 however remember their true meaning especially where educational processes are involved. 208

It is surprising that Eq. (3.29) actually accounts for the whole of electrodynamics beause all current electrodynamics problems can be solved using this equation. What is then a magnetic field? This is merely a convenient mathematical procedure which is not necessarily gives a correct result (e.g., in the case of parallelmoving charges). Now we can state that electrocurrent, rather than electromagnetic, waves travel in space. Their electric field and displacement current vectors are in the same plane and displaced by ?/2.

Any theory is dead unless important practical results are obtained of its basis. The use of the previously unknown transverse plasma resonance [14] is one of the most important practical results following from this study. ¹
