A Study on the Eigen-Property of the Cylindrical Coaxial Cavity by FEM

By Yeong Min Kim
Kyonggi University, Korea

Abstract- The eigen-properties of the cylindrical coaxial cavity have been investigated by FEM. The eigen-equation has been constructed basing on tangential edge vectors of the tetrahedral element. It was retreated with the shift-invert strategy to maintain the calculation stability. Krylov-Schur iteration method has been applied to it in order to obtain the eigen-pairs of TM and TE modes. Eigen-modes were calculated from the unitary similar transforming matrices of this iteration loop. Eigen-values have been determined from diagonal components of the Schur matrix. The eigen-pairs have been revealed as a result in the schematic representations for each modes. The eigen-modes were so complex that the surface features also have been shown in accompanying with them to identify their characteristics.

Keywords: eigen-pair, FEM, Krylov-Schur iteration method, TM, TE, Galerkin method, Helmholtz equation.

A Study on the Eigen-Property of the Cylindrical Coaxial Cavity by FEM

Yeong Min Kim

Abstract- The eigen-properties of the cylindrical coaxial cavity have been investigated by FEM. The eigen-equation has been constructed basing on tangential edge vectors of the tetrahedral element. It was retreated with the shift-invert strategy to maintain the calculation stability. Krylov-Schur iteration method has been applied to it in order to obtain the eigen-pairs of TM and TE modes. Eigen-modes were calculated from the unitary similar transforming matrices of this iteration loop. Eigen-values have been determined from diagonal components of the Schur matrix. The eigen-pairs have been visualized with the 3-Dim (Dimensional) schematic representations for each modes. The eigen-modes were so complex that the surface features also have been shown in accompanying with them to identify their characteristics.

Keywords: eigen-pair, FEM, Krylov-Schur iteration method, TM, TE, Galerkin method, Helmholtz equation

I. Introduction

It has been well known that the knowledge about eigen-mode is one of the most important thing designing the resonant cavity. Acquiring an information about the eigen-property is indispensable in the process of developing more valuable product. There are several factors influencing the eigen-property in the cavity. Among others, the geometrical structure has been considered as the most dominant factor influencing on the eigen-property. Its structure determines the eigen-mode which characterizes the resonant electromagnetic field. The cavity would be taken a variety of form in accordance with its applying purpose. Previously, we have studied the eigen-properties of cylindrical and rectangular resonant cavities using FEM (Finite Element method) [1] [2]. These studies have revealed the several prominent eigen-modes and corresponding eigen-values for each TM and TE modes. The spectra have been shown visually with the 3-Dim (Dimensional) schematic representation. These results have suggested that the similar method may be carried out on varied 3-dimensional cavities and give valuable information understanding the physical property of more complicating system. In this study, FEM has been performed on the cylindrical coaxial cavity as like the previous study. The mesh element was a simple tetrahedron and the shape functions were constructed with constant tangential edge vectors. The matrix eigen-equation was established basing on the vector Helmholtz equation. For a three-dimensional problem, the number of variables increases drastically comparing to a two-dimensional problem. It may be very difficult problem to calculate the huge dimensional matrix equation by common eigen-solving method. Krylov-Schur iteration method has been known as one of the most important and actively developing algorithms for calculating the large dimensional eigen-equation [3] [4]. This method compresses and transforms similarly the eigen-matrix into the Shur form. Even using personal computer, this method was easily carried out on the calculation obtaining the several prominent eigen-pairs. Accompanying with it, the shift-invert strategy add more helpful benefit to obtain the specific eigen-mode. So, Krylov-Schur iteration method has applied to the matrix eigen-equation in this study. As the results, the spectra for each eigen-pairs have been visualized with the schematic representations as like the previous study. The spectra were so complex that surface components of the field vector separated and presented side by side to each spectra.

II. Finite Element Formulation

The calculation for the eigen-mode is the same as describing in previous studies. The formulation can be followed by using either \( \mathbf{E} \) (electric field strength) or \( \mathbf{B} \) (magnetic field strength) field. For a convenience of calculation, only \( \mathbf{E} \) would be considered in the following discussion. The vector Helmholtz equation would be used in determining the wave property of the resonant cavity. It is described as following equation [5] [6]

\[
\nabla \times (\frac{1}{\varepsilon} \nabla \times \mathbf{E}) - k^2 \varepsilon_0 \mathbf{E} = 0
\]

where \( k \), \( \mu \), and \( \varepsilon \) is the wave number, relative permeability \( \mu/\mu_0 \) and relative permittivity \( \varepsilon/\varepsilon_0 \) respectively. The eigen-equation is constructed from FEM basing on the tetrahedral elemental mesh. The cylindrical coaxial resonant cavity and the tetrahedral mesh is shown in the Fig.1. In the calculation, the lateral surface of the cavity has been assumed to be PEC (perfect electric conductor). This boundary condition makes TM and normal derivative for TE components to be vanished at the lateral surface. The Galerkin method of weighted residual has been used to construct a linear equation [7]. The equation resulting from this method is given as following.

The six unknown parameters $e_1, ..., e_6$ are associated with tangential edges of the tetrahedral elemental mesh. Substituting equation (7) into equation (2), the eigen-equation of one tetrahedral element can be written in matrix form

$$[S_{el}][e] = k^2[T_{el}][e]$$

(8)

Where the element matrices are given by

$$[S_{el}] = \iiint \frac{1}{\mu_r} \nabla \times \vec{W} \cdot (\nabla \times \vec{E}) \, dV$$

(9)

$$[T_{el}] = e_r \iiint \vec{W} \cdot \vec{E} \, dV$$

(10)

The evaluation of the element matrix requires the curl product for each basis function $\vec{W}_m$

$$\nabla \times \vec{W}_m = \nabla \times (l_m (N_{m1} \nabla N_{m2} - N_{m2} \nabla N_{m1}))$$

$$= 2l_m \nabla N_{m1} \nabla N_{m2}$$

$$= 2l_m ((c_{m1}d_{m2} - c_{m2}d_{m1})\hat{x} + (b_{m1}d_{m2} - b_{m2}d_{m1})\hat{y})$$

$$+ (b_{m1}c_{m2} - b_{m2}c_{m1})\hat{z})$$

(11)

And from it

$$[S_{el}]_{mn} = 4l_m l_n V(\vec{w}_m \cdot \vec{w}_n)$$

(12)

To obtain the element matrix $[T_{el}]$, the scalar product between $\vec{W}_m$ and $\vec{W}_n$ may be calculated as

$$\vec{W}_m \cdot \vec{W}_n = l_m (N_{m1} \nabla N_{m2} - N_{m2} \nabla N_{m1})$$

$$\cdot l_n (N_{n1} \nabla N_{n2} - N_{n2} \nabla N_{n1})$$

$$= l_m l_n [N_{m1}N_{n1}\varphi_{m,n1} - N_{m1}N_{n2}\varphi_{m,n2} - N_{m2}N_{n1}\varphi_{m,n1} + N_{m2}N_{n2}\varphi_{m,n2}]$$

(13)

$$= l_m l_n [N_{m1}N_{n1}\varphi_{m,n1} - N_{m1}N_{n2}\varphi_{m,n2} - N_{m2}N_{n1}\varphi_{m,n1} + N_{m2}N_{n2}\varphi_{m,n2}]$$

(14)

Where $\varphi_{mi,nj} = \nabla N_{mi} \cdot \nabla N_{nj}$ is $b_{mi}b_{nj} + c_{mi}c_{nj} + d_{mi}d_{nj}$

In the process of $[T_{el}]$ calculation, following volume integration for 3-Dim simplex coordinates may be used

$$\iiint (N_1)^i (N_2)^j (N_3)^k \, dV$$

$$= \frac{3! i! j! k! l! m! n!}{(3 + i + j + k + l)!} V$$

(15)

These integrals can be simply summarized in the following matrix form $[8]$

$$[M_{ij}] = \frac{1}{V} \iiint N_i N_j \, dV = \frac{1}{20} \begin{bmatrix} 1 & 2 & 1 & 1 \\ 2 & 1 & 1 & 1 \\ 1 & 1 & 2 & 1 \\ 1 & 1 & 1 & 2 \end{bmatrix}$$

(16)

From the equations (13), (14) and (16), the element matrix can be written as following

$$[T_{el}]_{mn} = VM_{lm} \varphi_{m,n2}M_{m1,n1} - \varphi_{m,n2}M_{m1,n2} - \varphi_{m,n1}M_{m1,n2} + \varphi_{m,n1}M_{m2,n2}$$

(17)

These element matrices are assembled over all tetrahedral elements in the 3-Dim cavity to obtain a global eigen-matrix equation,

$$[S][e] = k^2[T][e]$$

(18)
III. Results and Discussion

The following discussion is similar to the previous studies. The same FEM formulation was applied to the cylindrical coaxial cavity. But it is confirmed that the mesh structure was differently constructed from these studies and the results sufficiently reflected on the characteristics of the present cavity.

In this study, FEM has been used to construct the eigen-equation. The variable of vector Helmholtz equation was the vector edge of the tetrahedral mesh. The vertices of the tetrahedron were arranged following the right hand rule to obtain the positively determinant value of the element mesh. The dimension of the eigen-matrix equation was so large that the Krylov-Schur iteration method has been used to obtain several prominent eigen-modes. The calculation was more efficiently promoted in finding specific eigen-pairs by imploiring the shift-invert strategy as following [9]

\[ \lambda[e] = \frac{[T]}{[S] - \sigma[\bar{T}]}[e] = [M][e] \]  

(19)

where \( \lambda = \frac{1}{k^2 - \sigma} \). As mentioned in the previous study, the sparsity and symmetry of the eigen-equation would be lost. But by this strategy, the convergent rate was further increased at the specific value \( \sigma \). The Krylov-Schur iteration method has been performed on this square matrix [M]. By this iteration method, the matrix [M] has been transformed into a Schur matrix. The eigen-modes were the column vectors of the similar transforming matrix which convert the square matrix [M] to the Shure form. The wave numbers were calculated by converting each diagonal component of the Schur matrix into values \( k^2 = \frac{1}{\lambda} - \sigma \). As a result, the eigen-pairs have been schematically represented in Fig. 3. The wave numbers were written in the blanket under each spectrum. As can be seen in the spectra, eigen-mode has shown the complicating distribution of electromagnetic fields. So, the surface components were separated from each spectra and positioned side by side to them. From these results, it could be identified that the modes type and wave numbers have been written under each spectra. From these results, it could be identified that the spectra reflect the characteristics of the coaxial cylindrical cavity.

IV. Conclusion

The 3-Dim eigen-equation of the cylindrical coaxial cavity has been constructed by FEM. Eigen-pairs have been calculated by applying the Krylov-Schur iteration method to the shift inverted matrix. As a result, the spectra have been represented schematically in the figure. To identify the mode type, the surface component were separated from the 3-Dim spectra. The mode type and wave numbers have been written under each spectra. From these results, it could be identified that the spectra reflect the characteristics of the coaxial cylindrical cavity.
