7 Abstract

3

5

Structural reliability analysis was carried out on the Mansonia altissima timber, to ascertain 8 its structural performance in timber roof truss system. Structural analysis of the timber truss 9 was in accordance with Eurocode 5 (2004) and was carried out under the Ultimate Limit State 10 of loading. A developed MATLAB (2010) programme was employed for reliability analysis of 11 the timber roof truss of Mansonia altissima timber so designed, to ascertain its level of safety 12 using GA-based First-Order Reliability Method. The uncertainties in the strength and load 13 variables were accommodated in the reliability analysis. The result of the analysis revealed 14 that the Joint failure mode is the critical safety index that is minimum safety index among the 15 failure modes of the truss under the design conditions. The Mansonia altissima timber was 16 found to be a satisfactory structural element for timber roof truss at depth of 75mm, breadth 17 of 50mm and under the ultimate limit state of loading with the corresponding of 2.58. 18 Sensitivity analysis proves that the degree of reliability of the timber roof truss can be 19 improved if crosssections of species, diameter of nail at joint, pitch of truss and loadings are 20 suitable selected. 21

23 Index terms— reliability analysis, GA-based form, roof truss, failure modes, mansonia altissima.

²⁴ 1 I. Introduction

he traditional way of dealing with uncertainties in design process is to use conservative values of the uncertain 25 quantities and/or safety factors in a deterministic approach. The shortcomings of this approach may become 26 more obvious when designing for loads with very high variability. It is not easy to account for all factors that 27 affect assessment of loads consistent with acceptable risk (Anthony, 1991; Afolayan, 1999 and. However, since no 28 structure may be free from the possibility of failure, loads must be designed to fit the risk. A deterministic design 29 approach does not an explicit consideration for this. A more meaningful treatment of uncertainties in structural 30 timber can be through a probability-based design philosophy, which has received considerable attention (Afolayan, 31 2005; Abejide, 2006; ??hmed et al., 2010; Kachalla and Kolo, 2012; Aguwa, 2013; ??itlevsen and Madsen, 2005). 32 Author ?: Civil Engineering Technology Federal Polytechnic Kaura Namoda. e-mail: smagaji2003@yahoo.com 33 34 Author ?: Civil Engineering Department, Ahmadu Bello University, Zaria, as structural components such as roof

trusses ??Ahmad et al., 2010). The tensile strength of the lower chord of a truss is considered the critical design
parameter ??Bostrom et al., 1999). It had been identified that joints in timber structures are the most critical
components that need special extensive research (Racher, 1995;Smith and Foliente, 2002;Riley and Sadek, 2003).

According to Frank and Philip (1997), bottom chord joints are located in areas such that they experience a small

bending moment, and are stressed primarily in tension. He determined the steel net section capacity of bottomchord joints of wood trusses subjected to tension and moment loading.

Genetic algorithm is intelligent search and optimization method that work very similar to the principles of natural evolution called Darwin's survival-of the fittest principles. If GA is incorporated in to reliability methods

5 III. STRUCTURAL RELIABILITY ANALYSIS

43 such as FORM, population of limit functions with different combination design variables are considered, and

44 safety index is obtained for each set. The sets of safety index are assembled and the minimum that is the globally 45 best and fittest is considered. Several generations are further considered through crossover, mutation and elitism

⁴⁵ best and fittest is considered. Several generations are further considered through crossover, mutation and elitism ⁴⁶ operation in GA until a convergent is achieved. This widen the search space for the global minimum (critical)

47 safety index (Mohammed and Abubakar, 2011; ??heng, 2007;Wang and Ghosn, 2005).

The Eurocode 5 design criteria of roof truss members subjected to combination of varying design actions are briefly reviewed. Identification of the significant failure modes was deterministically analysed and of failure modes (tension, compression, bending of the top and bottom chord) were established.

⁵¹ 2 a) Structural model

The analysed structural model of the truss system is shown in Fig. 1. It was assumed that the truss had a roof pitch of 350, spacing between the trusses of 1.2 m, Length of 7.2 m, dead load of 0.55 kN/m 2, fixed nailed length

of 90 mm, nail diameter of 4.0mm and dead-to-live load ratio of 0.275. The roofing material used was aluminium-

⁵⁵ roofing sheets. The connections The tensile and compressive properties of the timber are particularly important

when applying timber between the members were assumed to be pinned joints as stipulated in ??urocode 5 (2004). The following limit state functions were established from the structural analysis of the model.

⁵⁸ 3 II. Limit State Functions

- 59 i. Compression failure criterion The limit state function for compression is given as: $G(x) = (k \mod f c, 0, k)$? m
- ii. Tension failure criterion-? ci,d(1)

where k mod is modification factor for variation in density and moisture content. f c,0,k is the characteristic compressive strength parallel to grain. ? m is the timber material partial safety factor for strength, ? ci,d is the design compressive stress for members under compression that are members 4, 5, 6, 8 and 10.

The limit state function for tension is given as: $G(x) = (k \mod f t, 0, k)$? m

where f t,0,k is the characteristic tensile strength parallel to grain, ? ti,d is the design tensile stress for members under tension that are members 1, 2, 3, 7, 9 and 11.

67 -? ti,d

68 iii. Bending failure criterion

The following is the limit state function for bending is as following: $G(x) = (k \mod f m, k)$? m iv. Connection failure criterion -? mi.d(3)

f m,k is the characteristic bending strength, ? mi.d is the design bending stress for members under bending that include member 1, 2, 3, 4, 5, and 6.

77 2 15 . 1 2 1 5 1 2 2 1 2 1 5 1 2 2 ? ? ? (4)

78 wherek h k h f f . 1 . . 2 .

$_{^{79}}$ 4 = ?

T = The characteristic values for high yield moment using round wire nail can be deduced from the following expression: 6 . 2 . 180 600 d f M u k v = (5)

where S is the load effect in member; K mod is the composite modification factor taking into account deviations
 from normal load and climate conditions during the service life;

, m ? is partial safety factor for the material (1.3); n is number of fasteners; t i is depth of the timber species.
 The statistics of the design variables employed in the study suitable for targeted performance levels are shown
 in Table 1.

⁸⁹ 5 III. Structural Reliability Analysis

Analysis is aimed at a systematic consideration of the variability in the design variables. Assuming u is an independent, standard normal vector containing the parameters of the stress-strength interference and g(u) the state function representing the interference then according to Afolayan (2005) a measure of violation of such a state is P = P(u ? F) = P(g(u) ? 0) (7)

- where F is the failure domain. Equation (1) can be approximated to give (Gollwitzer et al., 1988; ??admanabhan, 2003):?? ð ??"ð ??" ? ? (?) (8)

- where ? can be set to 0.95 (Wang and Ghosn, 2005).

¹⁰¹ 6 IV. Results and Discussion

The force and stress in each member due to action loads was determined using resolution of forces. The critical 102 load at each joint was used in the analysis of the joints. The member-force, member-stress and formulated 103 model function for each member as presented in Table 2 were used in the reliability analysis. where (T) and (C) 104 represent tension and compression members respectively, l i is the length of member, ? is the dead-to-live load 105 ratio, b is breadth and t is depth of timber species. The result of the reliability analysis of the roof truss for 106 Mansonia altissima at the ultimate state of loading was presented in Table 3. The safety indices for the bending, 107 tension, compression and joint failure modes are 3.94, 2.92, 3.62 and 2.58 respectively. Joint failure mode is 108 the least failure mode hence predetermines the safety of the truss. The computed critical safety index of 2.58 109 agrees with Melchers (1987) who stated that target reliability index (? T) for timber members ranges from 2.0 110 to 3.0 with strong mean of 2.5. This implies that at this depth of section the timber roof truss is reliable under 111 specified conditions of loadings and geometric properties. However, the degree of reliability of the roof truss can 112 be improved if suitable cross-section is chosen (Benu and Sule, 2012). The sensitivity analysis was conducted 113 to ascertain the effect of some of design variables on the reliability of the truss. Fig. ?? shows the relationship 114 between safety index (?) and depth of section (t) for the timber roof truss of Mansonia altissima. An increase 115 in safety index (?) from 1.96 to 4.47 was recorded for joint failure mode as the depth was increased from 50mm 116 to 250mm respectively. The Joint failure mode has the least safety index among all the failure criteria for the 117 Mansonia altissima then followed by tension failure mode as shown in Fig. ?? The increase in safety index (?) 118 could be attributed to the increase in EI values, which increased the rigidity of the section (Aguwa, 2013). It is 119 worthy to note that at a larger depth, the structure may be very reliable but not economical because drying and 120 lifting will be a problem. Since structural safety must recognize financial burden involved in project execution 121 and general utility, the derived factors of safety are improved to balance conflicting aims of safety and economy 122 (Afolayan, 1999). 123

¹²⁴ 7 Global Journal of Researches in Engineering () Volume XVI ¹²⁵ Issue III Version I

Figure ??: Variation of safety index against depth of section for Mansonia altissima Fig. 3 shows the relationship 126 between depth of section and live load for the timber roof truss of Mansonia altissima at the ultimate limit state 127 of loading and at variable live load. An increase in the depth of section was recorded for all the failure modes 128 as the live increases. The result revealed that Joint failure mode is predominant which recorded an increase in 129 130 the depth of section from 105mm to 157mm as the live increases from 1.0kN/m to 7.0kN/m respectively. This 131 implies that live load has significant effect on the design depth of the roof truss members of Mansonia altissima. 132 At live load of 1.0kN/m, the bending and compression failure modes recorded the depth of sections of 75mm and 133 100mm respectively. As the live load increased to 5.0kN/m, the depth of sections for bending and compression converged to an approximate depth of section of 125mm. This implies that there are overlaps of behaviours 134 135 among the truss members at different live loads.

Fig. ?? shows the relationship between safety index and live load for timber roof truss of Mansonia altissima at the ultimate limit state of loading and at variable live load. A decrease in safety index (?) was recorded for all the failure modes with joint failure mode been predominant then followed by tension failure mode. A general consistent decrease in safety index was recorded for joint failure mode from 4.12 to 1.23 as the live load was increased from 1.0kN/m to 7.0kN/m respectively. This could be attributed to the increase in EI values, which increased the rigidity of the beam ??Aguwa and Sadiku, 2012). The members of the roof truss for Mansonia altissima is safe at a minimum breadth of 50mm under the specified design conditions.

Global Journal of Researches in Engineering () Volume XVI Issue III Version I Figure ?? : Variation of depth 143 of section with live load for Mansonia altissima Fig. 5 shows the relationship between safety index and diameter 144 of nail at joint for the timber roof truss of Mansonia altissima at the ultimate limit state of loading. An increase of 145 safety index was recorded from 3.98 to 4.4 as the diameter of nail increases from 3mm to 5mm. The safety index 146 then declined to 4.08 at 7 mm. This indicates that at the peak value of safety index the timber species reached 147 its highest capacity to resist the effect of diameter of nails and thus hold the timber pieces firmly together, but 148 beyond this critical diameter of nail the timber species have less resistant capacity to withstand any increase in 149 stresses due to increase in diameter of nails. It therefore tends to split. To avoid this split of timber piece EC 5 150 (2004) recommends predrilling of holes for large diameter of nails. 6 shows the relationship between safety index 151 and depth of section at various pitches of the timber roof truss of Mansonia altissima at the ultimate limit state 152 of loading. An increase in safety index (?) was recorded for all the failure modes at various pitches of the truss 153 154 with joint failure mode been predominant then followed by tension failure mode. It was observed that the pitch 155 of the truss has significant effect on safety of the timber roof truss. Considering joint failure mode an increase in safety index (?) was recorded from 1.25 to 3.81 as the depth of section of timber members increases 50mm to 156 250mm at the pitch of 10 0 respectively. However, as the pitch increases to 200, the safety index significantly 157 increases from 1.94 to 4.32 at the same ranges of the depth of section. This implied that for a pitched roof truss 158 large rafter slope lead to high reliability. 159

V. Conclusion 8 161

168

This paper has presented a reliability analysis of the timber roof truss using GA-based FORM, which searches 162

for the globally best and fittest solution. The failure modes of truss were checked and the uncertainties in the 163 strength and load variables were accommodated in the reliability analysis. It is shown that the Mansonia altissima 164

timber species is a reliable structural material and economical for the roof truss system at the specified ultimate 165

state of loading and geometrical parameters. The sensitivity analysis revealed that the safety index (?) is highly 166

sensitive to the depth of section, dead-to-live load ratio, diameter of nail and pitch of truss; hence, they are the 167 critical factors to be considered in design of timber roof truss. 1 2 3
