#### 7 Abstract

8 This paper focuses on studying a simulating framework for graphene based devices using

9 finite-difference time-domain (FDTD) method. Conventional FDTD is modified for graphene

<sup>10</sup> material using Surface Boundary Condition (SBC) where grapheme considered as a two

<sup>11</sup> dimensional ultra-thin conductive sheet. Then a Perfectly Matched Layer (PML) technique is

<sup>12</sup> implemented to terminate the computational grids. Using the surface boundary condition

<sup>13</sup> technique to model the graphene thin layer significantly reduces the computational cost

<sup>14</sup> compared to using the conventional FDTD. The given formulation is accompanied by required

15 validation.

### 18 1 I. INTRODUCTION

raphite materials come in a variety of forms. The 3-D graphite is the most commonly seen form, and the 1-D 19 carbon nanotube (CNT) has been another recent research interest, especially in composite materials. The newly 20 discovered graphene is the 2-D graphitic material, and is essentially the building block of the other forms. A 21 22 2-D crystal is in general hard to grow because as the lateral size of the crystal grows, the thermal vibration 23 also rapidly grows and diverges on a macroscopic scale, which forces the 2-D crystallites to morph into a stable 3-D structure [1]. Graphene has many outstanding properties. Its electrical properties include its high carrier 24 mobility, which is measured in various devices as 8000-10000 cm 2 V ?1 s ?1 and could reach 200000 cm 2 V 25 ?1 s ?1 in suspended grapheme [2]. Graphene's non-electronic properties bring a new dimension to graphene 26 research. It was found to have a breaking strength of 40 N/m, reaching the theoretical limit, as well as a Young' 27 smodulus of 1.0 TPa, which is a record value [3]. Graphene field-effect transistors (FET) and graphene wafer scale 28 integrated circuits have been fabricated and versatile graphene applications in EM and transformation optics has 29 been developed in recent years. 30

The nanopatch antenna simulation has done using FEKOand is discussed in [4]. The graphene transformation optics structures are discussed in [5] and simulation process has done using CST Microwave Studio. In both studies, the simulations are in the frequency domain, where the graphene conductivity is a complex number at a particular frequency. One can enter the conductivity value into the commercial software and run the simulation without making further modification to the software. Simulating graphenebased devices in time domain has several advantages. In this paper, the transient behavior of the device can be observed and studied and the result for a wide frequency band can be obtained from a single simulation in time domain.

The remainder of the paper is organized as follows: Section II introduces graphene transformation Optics.

FDTD Modeling for graphene is discussed in section III. Implementation of SBC in 2-D FDTD for Graphene
 are provided in section IV.PML loss parameters in discrete space are given in section V. Finally conclusion and

41 future work is described in section VI.

#### 42 2 II. GRAPHENE TRANSFORMATION OPTICS

43 Graphene has been investigated for its potential in material and transformation optics recently [5]. Graphene's 44 conductivity is a function of the chemical potential, which depends on gate voltage, and/or chemical doping 45 [6]. Its tunable conductivity allows it to shape electro-magnetic field into desired spatial patters which is a 46 great advantage over the noble material. Year 2017 F Abdullah Al Hadi ? & Syed Rafiee Abied ? e-mails: 47 alhadi@bubt.edu.bd, rafiee.abied@gmail.com Figure 2 shows alternatively; an uneven ground plane underneath 48 the graphene can be implemented to design the conductivity profile on the graphene.

#### 50 4 FDTD MODELING FOR GRAPHENE

Finite-Difference Time-Domain (FDTD) is a popular electromagnetic modeling technique. It is easy to understand, easy to implement in software, and since it is a time-domain technique it can cover a wide frequency range with a single simulation run. The FDTD method belongs in the general class of differential time domain numerical modeling methods. Maxwell's (differential form) equations are simply modified to central-difference equations, discretized and implemented in software. The equations are solved in a leap-frog manner; that is, the electric field is solved at a given instant in time, then the magnetic field are solved at the next instant in time, and the process is repeated over and over again.

### 58 5 a) Graphene Conductivity Model

The graphene conductivity (in unit of [S]) is given by the Kubo formula,??( $\delta$  ??",  $\delta$  ??", ??, ??, ??) = ?? ?? 2 59 60 ???? ? ???? ? ? ð ??"ð ??" ?? (???)?ð ??"ð ??" ?? (??) (ð ??"ð ??" ??? ??? ??? ) 2 ?4? ?? ? ? ? ? ? 2 ? 0 ? 0 ?????(1) 61 In equation (1),  $\delta$  ??" $\delta$  ??" ?? (??) = (?? (???????) ?? ?? ?? ?? ?? 1) ?? is the Fermi Dirac distribution, ?? 62 is the angular frequency in radians, ?? is the scattering rate is per sec, ?? is the temperature in Kelvin, -e is the 63 electron charge, ? is the band contribution and the second term is from the interband contribution?? ????????? 64 65 1 ð ??"ð ??" ??? 2??(2) 66 and the inter-band conductivity is as follows, ?? ?????????? (ð ??"ð ??", ?? ?? , ??, 0) = ??? ?? 2 4??? ln( 67  $2|?? ?? |?(\delta ??"\delta ??"??? 2??)? 2|?? ?? |+(\delta ??"\delta ??"??? 2??)? )(3)$ 68 The intra-band conductivity is mainly account for the low frequency electrical transport and inter-band 69 conductivity is for the optical excitations [8]. Taking the parameters used in graphene parallel plate waveguide, 70

71 ? c = 0.5eV, ? = 10 12 and T = 300K, the corresponding conductivity values are plotted in the figure given 72 below. We can see from Figure 5 that in the frequency up to 800 GHz, the value of ? intra dominates over that 73 of ? inter .Therefore ? inter can be ignored for most simulations below optical range.

To find the relative permittivity (?? ?? ) from the conductivity, the following equations are used. The results of the simulation curve are shown in figure 6.?? ?? = ?? ? ????? (9)?? ?? = ??  $\delta$  ??" $\delta$  ??"  $\delta$  ??" $\delta$  ??"  $\delta$  ??" $\delta$  ??"  $\delta$  ??" $\delta$  ??"  $\delta$  ??"  $\delta$  ??"  $\delta$  ??" $\delta$  ??"  $\delta$ 

# 6 IV. IMPLEMENTATION OF SBC IN 2-D FDTD FOR GRAPHENE

Let, the 2D computational domain is located in xy plane. So for TM mode, the fields components of electric and magnetic field are E z, H x and H y.

The ?? ?? field update equation for all other nodes is,?? ?? ??+0.5 (??, ??) = ?? ?? ???0.5 (??, ??) ? ??? 92 ????? 0 {?? ?? ?? (??, ?? + 1) ? ?? ?? ?? (??, ??)}(13)

<sup>93</sup> The ?? ?? field update equation for all other nodes is, V.

#### 94 7 PML LOSS PARAMETERS IN DISCRETE SPACE

95 The PML is usually backed by a PEC wall. The transmitted signal through the PML undergoes significant

<sup>96</sup> attenuation by the PML layer [9]. Again the reflected signal from the PEC wall also attenuated by the PML. In

a PML, reflection coefficient (R(?)) is a function of the incident angle (?) of the wave incidence on the PML. The reflection coefficient can be expressed as,??(??) =  $\exp(?2?? ?? ????????)(16)$ 

Here, ?? = wave impedance for free space ?? = wave incident angle ?? = depth of PML layer ?? ?? = conductivity of PML layer ??(??) is PML reflection error. It gives the relative magnitude of the spurious reflected wave, which enter back into the computational domain. The larger the??and ?? ?? , the lesser the reflection.

#### 102 **8 VI.**

## **103 9 CONCLUSION AND FUTURE WORK**

The simulated results matched with the analytical results. The given modified FDTD algorithm is able to simulate graphene based microwave problems where graphene is considered as very thin conductor. In order to extend the existing framework to model devices up to optical frequency, the inter band conductivity need to be taken into consideration. This can be done by applying the Pad'e approximation for graphene interband conductivity

[10]. For devices operating at the high terahertz frequency range, where the intra-band conductivity and the

inter-band conductivity have comparable magnitudes, both models are needed for accurate simulation results.
