Reduction of Bullwhip Effect in Auto Assembly Industry

By A.S.M. Tanvir Hasan, Muhammed Ridwanul Hoque, Nujhat Kawsari & Tomal Das
University of Engineering & Technology

Abstract - The main focal point of this study is to categories the reasons of Bullwhip Effect by fishbone diagram and tries to reduce bullwhip phenomenon. Three steps are followed here to resolve bullwhip effect. First, identify the causes. Fishbone diagram helps to classify the core reasons of it. The second part is to analyze the causes and discuss the effect of these causes and try to recommend some probable solutions. The third and last part is to observe the practical situation of bullwhip effect. Here, a case study is to be studied and apply the following solution of this supply chain system and observe how these solutions resolve the bullwhip phenomenon.

Abstract - The main focal point of this study is to categorize the reasons of Bullwhip Effect by fishbone diagram and tries to reduce bullwhip phenomenon. Three steps are followed here to resolve bullwhip effect. First, identify the causes. Fishbone diagram helps to classify the core reasons of it. The second part is to analyze the causes and discuss the effect of these causes and try to recommend some probable solutions. The third and last part is to observe the practical situation of bullwhip effect. Here, a case study is to be studied and apply the following solution of this supply chain system and observe how these solutions resolve the bullwhip phenomenon.

Keywords: supply chain, bullwhip effect, fishbone diagram.

I. INTRODUCTION

A Supply Chain (SC) includes all the participants and processes involved in the satisfaction of customer demand: transportation, storages, retailers, wholesalers, distributors and factories. A large number of participants, a variety of relations and processes, dynamics, the uncertainty and stochastic in material and information flow, and numerous managerial positions prove that Supply Chains should be considered as a complex system in which coordination is one of the key elements of management.

An important observation in supply chain management was made by Forrester (1961), who illustrated the effect of the variance amplification, called the bullwhip effect, in a series of case studies. The bullwhip effect is a tendency for small changes in end-consumer demand to be amplified as one move further up the supply chain. Common practical effects of this variance amplification were described in cases of companies Procter & Gamble and Hewlett-Packard, and are presented to students worldwide through the business game “Beer Game” developed on MIT (Sterman, 1989).

Logistics executives at Procter & Gamble (P&G) examined the order patterns for one of their best-selling products, Pampers. Its sales at retail stores were fluctuating, but the variability was certainly not excessive. However, as they examined the distributors' orders, the executives were surprised by the degree of variability. When they looked at P&G's orders of materials to their suppliers, such as 3M, they discovered that the swings were even greater. At first glance, the variability did not make sense. While the consumers, in this case, the babies, consumed diapers at a steady rate, the demand order variability in the supply chain were amplified as they moved up the supply chain. P&G called this phenomenon the "bullwhip" effect.

When Hewlett-Packard (HP) executives examined the sales of one of its printers at a major reseller, they found that there were, as expected, some fluctuations over time. However, when they examined the orders from the reseller, they observed much bigger swings. Also, to their surprise, they discovered that the orders from the printer division to the company's integrated circuit division had even greater fluctuations.

II. SUPPLY CHAIN

Supply chain refers to the chain of supply of goods from manufacturer to the customer. It consists of two individual and complete words namely- supply & chain. Supply stands for providing or to furnish something of need. According to the dictionary a chain means a series of connected units of metal which are used to make a link. Generally it refers to something that helps to create a link between two or more things. Hence the meaning of supply chain may be expressed by the phrase-An interlinked process of system to provide the customers with the required goods or service.

It is clear that supply chain includes every single point that complete the chain of supply such as supplier, manufacturer, distributor, retailer, customer etc. The supply chain of a company is called successful when the flow of material from one point to another is possible at an optimum cost as well as the final product is at customers’ hand at the right time.

This may seem to be contradictory at some extent. Providing service to the customer requires a good level of inventory and a shorter lead time. On the other hand if the inventory gets higher, the cost increases. The combination of these two is necessary to make a supply chain a success. For example Rahim Afrooz sells generators. Even if all know that transportation needs a certain lead time customers are not willing to wait that long. They want the service just in time. This is why the company has to maintain a minimum level of inventory depending upon their demand forecast. They are to choose what kind of
transportation is to be taken for the process. Air is such a medium that takes a little time at a relatively high price. On the contrary water-ship is not costly but takes more time to deliver product.

A very poor result can happen to a certain supply chain if it is attacked by the bullwhip effect. There are some reasons behind this vital effect. Whatever the causes are, they are not unsolvable. Proper coordination is a must to solve the problems. Only a successful supply chain can lead a business towards prosperity.

III. THE BULLWHIP EFFECT

In Supply Chain, Bullwhip is an important term. Actually it is a phenomenon. The Bullwhip Effect is one of the main reasons for the inefficiencies of Supply Chain. Mainly this phenomenon is created for lacking of coordination and passing necessary information. Bullwhip Effect causes the fluctuation of demand variable and this effect the overall Supply Chain very much. Customer, Retailer, Wholesaler and Manufacturer are much related to the affect of Bullwhip effect. But increasing and decreasing demand is highly responsible for bullwhip effect. But some causes can be identified.

1. Over reaction of the backlog orders.
2. Communication gap between the partners.
3. Lead time and delay times between order processing, demand, and receipt of products.
4. Order batching: technique for decreasing ordering costs due to price discounts for bulk ordering, shipping cost decrease by ordering full-truck loads, etc.
5. Limited order size.

Figure 1: Bullwhip Effect

For any company it is very necessary to manage the supply chain. The whole profit depends on it. So the symptom should be known. They are:

1. Huge inventory
2. Error or poor forecasting
3. Capacities(excessive or insufficient)
4. Unavailable products
5. Information gap

IV. CAUSES OF THE BULLWHIP EFFECT

Normally several causes are responsible for Bullwhip Effect in supply chain [2]. They are:

1. Demand forecast updating
2. Order batching
3. Price fluctuation
4. Rationing and shortage gaming

Fishbone diagram help us to detect these causes.

For example, if a manager uses, say, exponential smoothing (future forecast is always updated as demand increases) the order sent to the supplier reflects the amount needed to replenish the stocks to meet the requirements for future demands and safety stocks which might be considered necessary [2].

b) Order Batching

“Cost is to be minimized”, that is the main them of any company. So to reduce the fixed cost and setup cost, order batching is performed. Normally company wants to order in batches, so that the transportation cost will be minimized. To make more benefit influences a company for order batching. But Bullwhip effect is created when the forecast and order are not matched. For Example, Consider a periodic review stationary demand system with full backlogging at a retailer. The retailer would thus use an order up to level to monitor its inventory. This implies that he would order an amount equal to the preview cycle’s demand in every review cycle [3].

Order batching can be defined in sentence, which is “When the cost (fixed) is not zero, the ordering is uneconomical, but order batching is occurred.”
c) **Price Fluctuation**

Price fluctuation is another major cause of creating this bullwhip phenomenon. Normally more than 80% dealings between manufacturers and distributors of an industry follow an arrangement that is known as “forward by” arrangement. That is happen but the attractive price offer by the manufacturer. Forward buying is one of the main causes of price fluctuation. Different types of offers like discounts, quantity discounts, free offers rebates and coupons are normally given by the manufacturers and distributors. These causes enhance the price fluctuation very much.[1]

d) **Rationing & Shortage Gaming**

Rationing and shortage gaming is another common reason for bullwhip effect. Most of the demands are placed on the basis of forecasting or sometimes on prediction. Sometimes demands are many but the supply are not enough. In this case, the products are ordered more than its demand, so that the number of delivered products generally is the percentage of the number of products actually needed [4].

For example, a retailer actually needs 75 units, but he orders 100 units in the hope of getting 75 units. The main output of this rationing scheme is to make a situation that the demand is raising but actually that is totally artificial [5]. A retailer ordering based on what it expect to sell gets less and as a result loses sales, whereas a retailer that influences its order is rewarded.

e) **Competitor**

Competition is another backbone for creating bullwhip effect in supply chain. Every super market is competitor to the others. So they offer many services to their customers. Sometimes they offer discounts on many products or group of products. That is why bullwhip effect is enhanced.

f) **Inventory**

Inventory is also a responsible basis of bullwhip effect. For example, many companies make large stock of mango in its season. But their motive is to sell these mangos in offseason. That is why demand of the mango is increased and last of all; bullwhip effect is created in the whole supply chain.

---

V. **REAL SCENARIO OF BULLWHIP EFFECT (CASE STUDY-SWARAJ MAZDA LIMITED)**

Swaraj Mazda limited (SML) is a light commercial vehicle (LCV) manufacturing Company situated in Punjab. The information has taken the form of supply chain in SML as shown in (Figure 4). This inbound supply chain starts with 1st tier suppliers consisting of foreign suppliers and local suppliers. Since SML imports a variety of engine components: Information is collected from the customer directly. Internet can be used for that purpose. Customer will give the order on website to the dealer on which the company will have the direct right to access.

Table 1: Information of SML

In complete-knocked-down condition (CKD), therefore they constitute 1st tier suppliers. These components in raw material form or sub-assemblies reach the factory stores for assembly. After manufacturing/assembly the finished vehicles reach the factory stockyard for dispatches to zonal offices then zonal offices send the vehicles to the dealers. Customers place the orders and get the delivery from the dealers only and not from the zonal offices or the company directly. The whole supply chain involves the
flow of goods, cash and information and some time reverse logistics also in the form of returned defected and damaged vehicles.

![Physical flow of goods and Cash flow diagram]

**Figure 4**: Supply chain model of SML

### VI. Quantifying the Bullwhip Effect in SML

As shown in Figure 1, the outbound supply chain in SML extends from the factory to the zonal offices and from zonal offices to the dealers and then ultimate customers. Dealers collect orders from the customers and send to the zonal offices (ZO). ZOs after consolidating the orders send them to the factory for replenishment. Since, ZOs do not have any access to the customers’ demand data. Therefore the demand of ZOs for LCVs is forecasted on the basis of the demand of dealers generated from the customers. The variability in orders placed by the dealers is bound to be significantly higher than the variability in customers’ demand. The ZOs are forced to carry more inventories of finished vehicles than the dealers in order to meet the same service level as the retailer. This demand variability or bullwhip effect is more serious in large ZOs in south and Madhya Pradesh. This results in ineffective transportation, more carrying cost, more ordering cost and more manpower. Similarly company has to keep an extra inventory of raw materials, sub-optimal space and time. During the year 2005-06, the cumulative figure from customer demand to the SML demand to suppliers comes to a staggering figure of 2185 finished vehicles. These vehicles remain hidden at SML factorystock-yard (FSY), 10 zonal offices and 130 dealer points. If we quantify this figure into rupee value (An average of Rs 5 lacs), the total Bullwhip cost amounts to Rs 109.25 cr.

![Demand pattern of different stages]

**Figure 5**: Demand pattern of different stages

The total customer orders were 12975 during the year, but dealers demand stood at 13980 with an increase of 7.75%. Similarly zonal offices also inflated their demand to 14625, an increase of 12.71%. Finally SML’s orders to supplies were 15360 with 18.38% increase. As a whole the total demand inflation by SML over the customer demand was 16.84% Figure 4 shows the graphical view of it. The line inflates each time when the demand travels up in supply chain.

### VII. Coordination on Performance in SML

SML experienced complete lack of coordination, since each stage in the supply chain wanted to optimize its local objectives without considering the impact on the complete supply chain. It hurt the performance of the entire supply chain and ultimately the total supply chain profits were less than what could be achieved through coordination. SML receives demand information even during periods of time in which the dealer does not order. Therefore SML is suffering from ‘Extended Bullwhip Effect’. The following bullwhip ill effects were seen.

**Table 2**: Orders of different stages

VIII. REDUCTION OF BULLWHIP EFFECT

We can try to give many ways to solve the bullwhip effect. Here SML can be a nice way to solve that example that we have mentioned previously. SML witnessed following main obstacles to coordination in the supply chain [6]:

1. Lack of information
2. Forecasting based on orders and not on customer demand and
3. Push based production system

The following damage control measures have been adopted:

a) Share the Information

SML and its supply chain partners are in progress to use CPFR (collaborative planning, forecasting and replenishment) for information sharing and coordination. Now internet is the main way to place order. At the time for forwarding the demand to the zonal offices, the dealers also take help from internet. Here 54.63 days and 437 man hours are saved. (2185/40) = 54.63 days and 54.63x8 = 437 man hours

b) Push pull system

Push-pull production system can be very effective. The material is being pushed through assembly, but the whole vehicle is pulled through actual orders. Mainly this is monitored by forecasting. The pull-through replenishes what is being sold from the stockyard. The production and distribution depend on the demand. For this reason they are highly related with the customer demand than forecast demand. The main strategy in SML is to avoid obstacle of large fixed and working capital in finished vehicles. SML tries to fill the order after receiving order from zonal office. Now SML has stopped inflating the demand from zonal offices.

c) Demand generation module

Here the zonal office places their order with the factory by internet. Demand is submitted separately for each model. First adjustment is needed the order fulfilled in the past one week. Usually a distributed order is produced, which is a consolidation of all the orders received during the past one week. This order generated ultimately determines the dispatch from the factory and the sales in the coming week. Depending on the backorders, customers, the required buffer stock, and the available stock, the order communicates with the factory.

Order from Zonal office = Dealer/Customer order + Backorders + Required buffer Stock - Available Stock

d) Allocation Module

In this module, allocation of vehicles to the dealer is made according with the. After the day’s production run, allocation is done. For each model, the stock has to perfect for meeting the demand fully. Available stocks are delivered for the lacking of actual stocks. Demand and supply for each model is measured independently. And shortfall in the supply of one model is not made up by extra supply in any other model. The allocated stocks are supplied to their destination.

e) Inventory Placement

The company maintains 10 zonal offices throughout the country; the main purpose is to reduce delivery times to its customers. A higher than expected demand from one zone /region can be offset by a lower than expected demand from another. ‘Forward placement approach’ is followed by the company, which means locating stock closer to customers at a zonal office and dealer’s stockyard (Figure 4). Forward placement has an advantage of faster delivery times in the order fulfillment process; consequently service to the customer is quicker [6].

f) Distribution Module

Factory Stockyard (FSY): In the company, FSY is located itself and wholly owned by SML. All the vehicles are directly dispatched to the FSY and this is happened after assembly. The advantage comes from “inventory pooling”, which helps to make reduction in inventory and safety stock. That is happened for the merging of variable demands from the zonal offices.

Zonal offices (ZO): ZOs are company owned and operated. The importance of cycle time and control over order accuracy drove this decision to invest in facilities at zonal offices.

Dealers: The Company deals with a vast network having 130 dealers. A dealer team associated with the zonal offices helps the supervisors in carrying out survey and making true forecasts of the vehicles they also act as a link between the dealers and the zonal offices. The customers place their orders with dealers,
which are notified to the zonal offices. And further the zonal offices after compiling these orders send to the company for replenishments [6].

![Distribution Module](image)

**Figure 5 : Distribution Module**

**g) Hub & Spoke approach of information sharing**

Hub and spoke approach are also followed by the SML. Each spoke acts as a connection to a member of the supply chain. All the members of supply chain pass the information to a central hub representing zonal offices and each member has access to all information provided by the other members. By sharing this information, all supply chain partners can see the changes occurring anywhere in the supply chain and respond to those changes instantly. This information sharing has been made possible with the use of electronic data interchange (EDI) and Internet. This has resulted into following benefits to SML:

1. Quick information
2. Reduction of paperwork
3. Improved billing
4. Customer service improvement
5. Competitive advantage
6. Error free demand forecasting
7. Minimize the cycle time in receiving projected and actual demand information
8. Establish the monitoring of actual demand for product to as near a real time basis as possible.
9. Understand product demand patterns at each stage of the supply chain.
10. Minimize or eliminate information queues that create information flow delays.
11. Eliminate inventory replenishment methods that launch demand lumps into the supply chain.
12. Identify, and preferably, eliminate the cause of customer order reductions or cancellations.

Finally, the generous return policies that manufacturers offer retailers aggravate gaming. Without a penalty, retailers will continue to exaggerate their needs and cancel orders. Not surprisingly, some computer manufacturers are beginning to enforce more stringent cancellation policies.

**IX. Conclusion**

In this paper, we have tried to focus how ‘Bullwhip Effect’ is created in Supply Chain. With the help of an example we tried present the overall situation of Bullwhip effect in Supply Chain. We also try to resolve the bullwhip effect by several methods. Here we can see that, the lead time of an order can amplify the variability.
