Prashantha Kumar H.G ? , Asst. Prof. Mohan Kumar.S ? & Prof. Keerthiprasad K.S ? Within the last few 15 years there has been a rapid increase in the utilization of aluminium-silicon alloys, particularly in the automobile 16 industries, due to their high strength to weight ratio, high wear resistance, low density and low coefficient of 17 thermal expansion. The advancements in the field of application make the study of their wear and tensile 18 behaviour of utmost importance. In this present investigation, Aluminium based alloys containing 12% weight of 19 Silicon were synthesized using Centrifugal casting method. In case of this centrifugal process the molten metal 20 is poured in to the mould rotating at different rotational speeds. The centrifugal force helps in feeding and 21 positioning metal in the mould. The product produced by centrifugal casting has a good quality, dimensional 22 accuracy as Centrifugal casting results in denser and cleaner metal as heavier metal is thrown to parts of the 23 mould away from the centrifugal action removes unwanted inclusions, dross, cleaner casting, and material that 24 contains shrinkage, which can be machined away. Study of microstructure has showed the presence of primary 25 silicon. Hardness is compared with the different casting speeds. Tensile tests were carried out with universal 26 testing machine. Yield strength and ultimate tensile strength are studied for different rotational speeds. Wear 27 behavior was studied and resistance to wear is analyzed. The worn surfaces were analyzed. 28

²⁹ 2 Introduction

entrifugal casting is a casting technique that is typically used to cast thin walled cylinders. It is noted for the high
 quality of the results attainable, particularly for precise control of their metallurgy and crystal structure. Unlike
 most other casting techniques, centrifugal casting is chiefly used to manufacture stock materials in standard sizes
 for further machining, rather than shaped parts tailored to a particular end-use.

Centrifugal casting consists of producing castings by causing molten metal to solidify in rotating moulds. The 34 35 speed of the rotation and metal pouring rate vary with the alloy and size and shape being cast. The following 36 operations include in centrifugal castingrotation of mold at a known speed, pouring the molten metal, proper 37 solidification rate, and extraction of the casting from the mold. Centrifugal are relatively free from gas and shrinkage porosity. In centrifugal casting, a permanent mold is rotated continuously about its axis at high speeds 38 (200 to 2000 rpm) as the molten metal is poured. The molten metal is centrifugally thrown towards the inside 39 mold wall, where it solidifies after cooling. The casting is usually a fine-grained casting with a very finegrained 40 outer diameter, owing to chilling against the mould surface. Impurities and inclusions are thrown to the surface 41 of the inside diameter, which can be machined away. Centrifugal casting results in denser and cleaner metal as 42 heavier metal is thrown to parts of the mould away from the centre of rotation and the lighter impurities like 43

slag, oxides and inclusion are squeezed out to the centre. The castings produced have a close grain structure, 44 good detail, high density and superior mechanical properties. 45

In recent years aluminium alloys are widely used in automotive industries. This is particularly due to the 46 real need to weight saving for more reduction of fuel consumption. The typical alloying elements are copper, 47 magnesium, manganese, silicon, and zinc. Surfaces of aluminium alloys have a brilliant lustre in dry environment 48 due to the formation of a shielding layer of aluminium oxide. Aluminium alloy of 4xxx series, containing major 49 elemental additives of Si, are now being used to replace steel panels if various automobile industries. Due to such 50 reasons, these alloys were subject of several scientific studies in the past few years. 51

Silicon also has a low density (2.34 g cm^{-3}) , which may be an advantage in reducing the total weight of the cast component. Silicon has a very low solubility in aluminium; it therefore precipitates as virtually pure silicon, 53 which is hard and hence improves the abrasion resistance. Aluminium-silicon alloys form a eutectic at 12.6 wt%silicon, the eutectic temperature being 577°C. This denotes a typical composition for a casting alloy because 55 it has the lowest possible melting temperature [6]. Al-Si alloys containing more than about 12% Si exhibit a 56 hypereutectic microstructure normally containing primary silicon phase in a eutectic matrix [10]. Wislei R. Osório et. al [13] studied the effect of microstructure on mechanical properties for Al-9wt% Si.

Experimental Set Up 4 61

Actual centrifugal casting set up as shown in fig. 1 Here a mild steel mould of dimensions 81mm in inner diameter 62 and 88mm in length with wall thickness on 10mm is connected to a motor of 2HP through a shaft. The mould is 63 rotated precisely 20 to 2000 without vibrations. The material was prepared to study the influence of rotational 64 speed on cast. Aluminium is melted in a pit furnace heated to a 720 degree Celsius temperature with 200 degree 65 Celsius super heat. After skimming dross, it was poured into the rotating mould quickly. After a few seconds 66 the motor is turned off and casting pulled out, casting thickness of the cast was controlled by taking calculated 67 68 amount of metal .these casting were made for different speeds.

III. 5 69

6 Experiments 70

Charging calculated amount of Al &Si into Graphite crucible pit furnace and temperature of about 720?C is 71 maintained for few seconds till it turns to molten boiling temperature 200 ?C maintained for few seconds. This 72 process is to remove absorbed gasses. Hexachloroethane (C2Cl6) in tablets form are used a mild steel mould is 73 used. It is Connected to a 2HP motor can rotate at 0 to 2000 rpm till it get steady then setting the RPM of the 74 mould ie 400, 600, 800, 1000, 1400,1600,1800. Then pouring the Al-Si 12% molten into mould, It will get solidify 75 within 8 to 10 sec. Solidified cast is taken out from the mould and used for further analysis. 76

7 **Results and Discussion** 77

Experiments are carried out to study the influence of rotational speed on formation of full hollow cylinder 78 and their effects on mechanical properties. Al-Si alloys (12%) are used as study materials. These melts are 79 centrifugally cast at different rotational speeds to get 8 mm thick hollow cylinders. During casting of 8 mm 80 81 thick hollow cylinder at lower speeds ie, at 200 RPM and 400 RPM the speed not enough to lift the melt. 82 Very poor cylinder with non uniform distribution of molten metal and irregular shape is formed. At 600 RPM uniform hollow cylinder is formed it has poor inner surface with non uniform thickness. At 800 RPM a cylinder 83 formed with poor inner surface. At 1000 RPM a good cast is formed with good inner surface and mechanical 84 properties compare to than at 800 RPM. At 1200 RPM & 1400 RPM higher centrifugal force tends to lift the 85 melt poured and also impression of raining are observed due to high fluidity. a) Microstructure of Al-12%Si 86 alloy Metallographic preparation, sequential steps have to be performed to prepare Al-12%Si for micro structural 87 investigation are involved careful selection of sectioning, mounting, grinding, polishing, and etching procedures 88 is required, and each step must be optimized for each. The microstructures shown in the figure ??3 at across 89 the section of the casting, under various rotational speeds, it may be seen that more-or-less rounded particles 90 of aluminium (light areas, ?-solid solution) are crystallized, which are surrounded by fine eutectic silicon (dark 91 92 areas). Here, silicon has networked structure. The silicon has long rod like structure. Here the primary silicon 93 appears as coarse polyhedral particles. In addition, presence of primary silicon is also observed in the Al-12% 94 Si, although the size and volume fraction of the primary silicon is more at the outer diameter, as compared to 95 inner diameter of the different speed alloys. It was observed that the rotational speed of the mould has profound influence on the microstructure of Al-12%Si alloys. It is found that the grooves are along the sliding direction, 96 but not many cracks are seen. However, crack propagation is seen along the same direction as sliding. With 97 presence of Si content hardness of the material has increased. Deeper grooves in dry sliding condition may be 98 assigned to the abrasion of Si particles that have forced the Silicon in platelet form, for which deeper grooves 99 are produced. Whereas for Al-12% Si alloy, the height loss was increasing when the load increasing, and also 100

height loss is decreasing with the increasing the casting speeds. Similar trends in height loss for all other loads
 are observed.

104 The values of co-efficient of friction obtained from the experiment and friction behaviour is illustrated in

¹⁰⁵ 9 d) Tensile Test Results

From the load and elongation values, obtained from the universal testing machine, corresponding engineering 106 stress and engineering strain were calculated and plotted to get stress vs. strain curves for different samples of 107 Al-12%Si alloys. The micro hardness tests of all the samples were conducted using a Vicker's hardness testing 108 109 machine with a dwell time of 10 s and applied load of 0.1kgf (P) during the tests. For each specimen indentations were taken at inner and outer and value is reported. The following table shows the calculated Vickers hardness 110 number (VHN). The Vickers hardness numbers (VHN) for Al-12% Si for different speeds are found to be range 111 from 55to75. ??ig 8.a shows the hardness at outer and inner surface, and it is found that hardness at outer is 112 slightly more compare to that of inner surface at the cast, this is due to concentration of Si particles is more at 113 outer surface. 5. The height loss due to wear decreases when the increase in rotational speed of the cast. 6. The 114 hardness increase marginally with increase in rotational speed of the cast. 115

116 10 Researches in Engineering

117

The modulus of elasticity is calculated from the stress strain curve for all rotational speeds alloy and the values are compared, it shows decreasing with the increasing in the rotational speed of the casting.
V.

121 **11 Conclusions**

1. The present study rotational speed is one of the significant parameters in controlling the size and distribution of aluminium and silicon particles. 2. With the increase of rotational speed to the optimum value, there was a remarkable improvement in the microstructure, where a fine equiaxed structure was formed. The microstructure for the specimens rotated at below and above this optimum speed. 3. Wear behaviour is dependent on applied load, sliding speed mainly. However, the wear rate increases with increase in the load. 4. Hardness of the Al-Si alloy increases with the increase in rotational speed of the cast.

8. Tensile strength also increases marginally with increase in rotational speed. 9. Yield strength and ultimate tensile strength increases with the increase in the rotational speed of the cast. 10. Total elongation decreases with the increase of rotational speed of the cast. 12^{3}
