Abstract

The term "Levitation" refers to a class of technologies that uses magnetic levitation to propel vehicles with magnets rather than with wheels, axles and bearings. Maglev (derived from magnetic levitation) uses magnetic levitation to propel vehicles. With maglev, a vehicle is levitated a short distance away from a "guide way" using magnets to create both lift and thrust. High-speed maglev trains promise dramatic improvements for human travel widespread adoption occurs. Maglev trains move more smoothly and somewhat more quietly than wheeled mass transit systems. Their nonreliance on friction means that acceleration and deceleration can surpass that of wheeled transports, and they are unaffected by weather. The power needed for levitation is typically not a large percentage of the overall energy consumption. Most of the power is used to overcome air resistance (drag). Although conventional wheeled transportation can go very fast, maglev allows routine use of higher top speeds than conventional rail, and this type holds the speed record for rail transportation. Vacuum tube train systems might hypothetically allow maglev trains to attain speeds in a different order of magnitude, but no such tracks have ever been built. Compared to conventional wheeled trains, differences in construction affect the economics of maglev trains.

Index terms— maglev levitation, propel, vehicle, trains, vacuum tube.

1 Review of Magnetic Levitation (MAGLEV): A Technology to Propel Vehicles with Magnets

Abstract -The term "Levitation" refers to a class of technologies that uses magnetic levitation to propel vehicles with magnets rather than with wheels, axles and bearings. Maglev (derived from magnetic levitation) uses magnetic levitation to propel vehicles. With maglev, a vehicle is levitated a short distance away from a "guide way" using magnets to create both lift and thrust. High-speed maglev trains promise dramatic improvements for human travel widespread adoption occurs.

Maglev trains move more smoothly and somewhat more quietly than wheeled mass transit systems. Their nonreliance on friction means that acceleration and deceleration can surpass that of wheeled transports, and they are unaffected by weather. The power needed for levitation is typically not a large percentage of the overall energy consumption. Most of the power is used to overcome air resistance (drag). Although conventional wheeled transportation can go very fast, maglev allows routine use of higher top speeds than conventional rail, and this type holds the speed record for rail transportation. Vacuum tube train systems might hypothetically allow maglev trains to attain speeds in a different order of magnitude, but no such tracks have ever been built. Compared to conventional wheeled trains, differences in construction affect the economics of maglev trains. With wheeled trains at very high speeds, the wear and tear from friction along with the concentrated pounding from wheels on rails accelerates equipment deterioration and prevents mechanically-based train systems from routinely achieving

42 higher speeds. Conversely, maglev tracks have historically been found to be much more expensive to construct,
43 but require less maintenance and have low ongoing costs. Across the world, Engineering has the common language
44 and common goal- "Improving the Quality of Life" of mankind without any boundary restrictions. To bring about
45 this much needed change, Science and Technology need transformation by the frantic pace of market dynamics.
46 What we need today is "Change Leaders" to bring about innovation, growth and a totally new work culture.
47 Levitation is one such remarkable technology that is revolutionizing the technology to propel vehicles:

48 **2 ?**

49 In the present work, extensive literature survey has been carried out A demo model has been prepared and the
50 same has been put to operation. The results are very encouraging .Maglev trains use magnets to levitate and
51 propel the trains forward.

52 ? Only the part of the track that is used will be electrified, so no energy is wasted.

53 **3 ?**

54 Since there is no friction these trains can reach high speeds.

55 **4 ?**

56 It is a safe and efficient way to travel.

57 **5 ?**

58 Governments have different feedbacks about the technology. Some countries, like China, have embraced it and
59 others like Germany have balked at the expense.

60 Introduction alev (derived from magnetic levitation) uses magnetic levitation to propel vehicles with magnets
61 rather than with wheels, axles and bearings. With maglev, a vehicle is levitated a short distance away from a
62 guide way using magnets to create both lift and thrust. High-speed maglev trains promise dramatic improvements
63 for human travel if widespread adoption occurs.

64 Maglev trains move more smoothly and somewhat more quietly than wheeled mass transit systems. Their
65 non-reliance on friction means that acceleration and deceleration can surpass that of wheeled transports, and
66 they are unaffected by weather. The power needed for levitation is typically not a large percentage of the overall
67 energy consumption most of the power is used to overcome air resistance (drag), as with any other high-speed
68 form of transport. Although conventional wheeled transportation can go very fast, maglev allows routine use of
69 higher top speeds than conventional rail, and this type holds the speed record for rail transportation. Vacuum
70 tube train systems might hypothetically allow maglev trains to attain speeds in a different order of magnitude,
71 but no such tracks have ever been built.

72 **6 II.**

73 **7 Description**

74 ? Principle of Maglev Maglev is a system in which the vehicle runs levitated from the guide way (corresponding
75 to the rail tracks of conventional railways) by using electromagnetic forces between superconducting magnets on
76 board the vehicle and coils on the ground. The following is a general explanation of the principle of Maglev.

77 **8 a) Principle of magnetic levitation**

78 The "8" figured levitation coils are installed on the sidewalls of the guide way. When the on-board superconducting
79 magnets pass at a high speed about several centimeters below the center of these coils, an electric current is
80 induced within the coils, which then acts as electromagnet temporarily. As a result, there are forces which push
81 the superconducting magnet upwards and ones which pull them upwards simultaneously, thereby levitating the
82 Maglev vehicle.

83 **9 b) Principle of lateral guidance**

84 The levitation coils facing each other are connected under the guide way, constituting a loop. When a running
85 Maglev vehicle, that is a super conducting magnet, displaces laterally, an electric current is induced in the loop,
86 resulting in a repulsive force acting on the levitation coils of the side near the car and attractive force acting on
87 the levitation coils of the side farther apart from the car. Thus, a running car is always located at the center of
88 the guide way.

89 **10 c) Principle of Propulsion**

90 A repulsive force and an attractive force induced between the magnets are used to propel the vehicle
91 (superconducting magnet). The propulsion coils located on the sidewalls on both sides of the guide way are
92 energized by a three-phase alternating current from a substation, creating a shifting magnetic field on the guide

93 way. The on-board superconducting magnets are attracted and pushed by the shifting field, propelling the Maglev
94 vehicle.

95 11 III.

96 12 Basic Concept

97 Magnets repel each other when they're placed with their like poles together because they create a magnetic field
98 when they're created. While scientists don't rightly know why electromagnetic fields take the shape that they
99 do, their general consensus states that the field leaves one pole and tries to reach the nearest opposite pole that
100 it can, and when you place the like poles together the opposing fields repel one another. ? Make the train of
101 pine wood and stick the magnets on them also in the same way and maintain equal distance.

102 V.

103 13 Procedure for Assembly

104 ? Place the track on flat base of Sagwan wood.

105 ? The two tracks should be placed in such a way that the magnets of the two tracks are not in the same line.

106 ? Now place the guide rails on each side of the tracks in such a way that it prevents the sideward motion of
107 the train. ? After that place the train in centre position.

108 ? Remove 1 guide rail after the train has levitated.

109 ? Place some weight on the levitating train.

110 ? Check if the weight is balanced by the magnetic levitation force.

111 Pictures of demo model created by our team in mechanical workshops, SRMGPC levitation can be traced back
112 to John Mitchell where he noticed the repulsion of two magnets when the same pole of each was put together.

113 Early 1900s -Emile Bachelet in France and Frank Goddard in the United States discussed the possibility of
114 using magnetically levitated vehicles for high speed transport.

115 1922 -Hermann Kemper in Germany pioneered attractive-mode (EMS) Maglev and received a patent for
116 magnetic levitation of trains in 1934.

117 1934 -On August 14, Hermann Kemper of Germany receives a patent for the magnetic levitation of trains.

118 1962 -Research of linear motor propulsion and non-contact run started.

119 1965 -Maglev development in the U.S. began as a result of the High-Speed Ground Transportation (HSGT)
120 Act of 1965.

121 1966 -In the USA, James Powell and Gordon Danby propose the first practical system for magnetically levitated
122 transport, using superconducting magnets located on moving vehicles to induce currents in normal aluminum
123 loops on a guideway. The moving vehicles are automatically levitated and stabilized, both vertically and laterally,
124 as they move along the guideway. The vehicles are magnetically propelled along the guideway by a small AC
125 current. The original Powell-Danby maglev inventions form the basis for the maglev system in Japan, which is
126 currently being demonstrated in Yamanashi Prefecture, Japan. Powell and Danby have subsequently developed
127 new Maglev inventions that form the basis for their second generation M-2000 System. Powell and Danby were
128 awarded the 2000 Benjamin Franklin Medal in Engineering by the Franklin Institute for their work on EDS
129 Maglev.

130 1969 -Groups from Stanford, Atomics International and Sandia developed a continuous-sheet guide way (CSG)
131 concept.

132 1970 -Study of electro dynamic levitation systems using superconducting magnets started formally.

133 1972 -LSM-propulsion experimental superconducting Maglev test vehicle (LSM200) succeeded in levitated run.
134 LIM-propulsion experimental vehicle (ML100) succeeded in levitated run.

135 1977 -April, Miyazaki, Japan 7 km. maglev test track was opened. In July, test run of ML-500 inverted-T
136 guide way started at the Miyazaki Test Track.

137 1979 -In January, a simulated tunnel run tested. May, a run with helium refrigerator on-board tested (ML-
138 500R) and in December, a run of 517 km/h run was attained. (321 MPH).

139 1980 -November, a test run of MLU001 on Utype guide way started on the Miyazaki Maglev Test Track in
140 Japan.

141 1982 -November, a manned two-car train test run started.

142 1984 -Research on the idea was quickly started and a small train was unveiled in Birmingham, England. It
143 was used to ferry people between the town's airport and the city's main train station.

144 1986 -December, a three-car train registered 352.4 km/h run. (??19 2003 -March, longer traveled distance
145 1,219 km in a day was attained. July, cumulative traveled distance exceeded 300,000km and the number of
146 passengers for Maglev trial ride exceeded 50,000 persons. November, longest traveled distance 2,876 km in a day
147 was attained. December, the MLX01 arranged in a three-car train set attained 581 km/h (manned).

148 2004 -August, the number of passengers for Maglev trial ride exceeded 80,000 persons. October, the cumulative
149 traveled distance exceeded 400,000 km. November, a test of two trains passing each other at a maximum relative
150 speed of 1,026 km/h.

14 -January, His Imperial Highness Crown

151 Prince Naruhito experienced Maglev trial ride.

152 2006 -Chinese developers unveiled the world's first full-permanent magnetic levitation (Maglev) wind power
153 generator at the Wind Power Asia Exhibition 2006 held June 28 in Beijing, according to Xinhua News. On
154 August 11, the Shanghai maglev caught fire from an onboard battery. September 22, an elevated Transrapid
155 train collided with a maintenance vehicle on a test run in Lathen (Lower Saxony / north-western Germany).
156 Twenty-three people were killed and ten were injured.

157 2008 -Elevators controlled by magnetic levitation are set to debut.

161

16 The Technology a) Magnet

162 A magnet is any object that has a magnetic field. It attracts ferrous objects like pieces of iron, steel, nickel and
163 cobalt. In the early days, the Greeks observed that the naturally occurring 'lodestone' attracted iron pieces.
164 From that day onwards began the journey into the discovery of magnets.

165 These days' magnets are made artificially in various shapes and sizes depending on their use. One of the
166 most common magnets -the bar magnet -is a long, rectangular bar of uniform cross-section that attracts pieces
167 of ferrous objects. The magnetic compass needle is also commonly used. The compass needle is a tiny magnet
168 which is free to move horizontally of the compass needle points in the North direction and the other end points
169 in the South direction.

170 The end of a freely pivoted magnet will always point in the North-South direction. The end that points in
171 the North is called the North Pole of the magnet and the end that points south is called the South Pole of the
172 magnet. It has been proven by experiments that like magnetic poles repel each other whereas unlike poles attract
173 each other.
174

17 i. Magnetic Fields

175 The space surrounding a magnet, in which magnetic force is exerted, is called a magnetic field. If a bar magnet
176 is placed in such a field, it will experience magnetic forces.

177 ii. Magnetic Lines of Force Just as an electric field is described by drawing the electric lines of force, in the
178 same way, a magnetic field is described by drawing the magnetic lines of force. When a small north magnetic
179 pole is placed in the magnetic field by a magnet, it will experience force. influence of a magnetic field is called a
180 magnetic line of force. In other words, the magnetic lines of force are the lines drawn in a magnetic field along
181 which a north magnetic pole would move.

182 The direction of a magnetic line of force at any point gives the direction of the magnetic force on a north pole
183 placed at that point. Since the direction of magnetic line of force is the direction of force on a North Pole, so the
184 magnetic lines of force always begin on the N-pole of a magnet and end on the S-pole of the magnet. A small
185 magnetic compass when moved along a line of force always sets itself along the line tangential to it. So, a line
186 drawn from the South Pole of the compass to its North Pole indicates the direction of the magnetic field. Pole of
187 a magnet and end at its South Pole. 2. The magnetic lines of force come closer to one another near the poles of
188 a magnet but they are widely separated at other places. 3. The magnetic lines of force do not intersect (or cross)
189 one another. 4. When a magnetic compass is placed at different points on a magnetic line of force, it aligns itself
190 along the tangent to the line of force at that point. 5. These are just some of the basic concepts of magnetism.
191 One cannot possibly grasp the depth and appreciate the versatility of magnets without reading more about the
192 uses of magnets, the
193

18) Types of Magnets

194 There are various types of magnets depending on their properties. Some of the most well known are listed below.
195

19 i. Permanent Magnets

196 These are the most common type of magnets that we know and interact with in our daily lives. E.g. The magnets
197 used in our refrigerators. These magnets are permanent in the sense that once they have been magnetized they
198 retain a certain degree of magnetism. Permanent magnets are generally made of ferromagnetic material. Such
199 material consists of atoms and molecules that each have a magnetic field and are positioned to reinforce each
200 other. NIB and SmCo are the strongest types of magnets and are very difficult to demagnetize. They are also
201 known as rare earth magnets since their compounds come from the rare earth or Lathanoid series of elements in
202 the periodic table. The 1970s and 80s saw the development of these magnets.

203 Permanent Magnets can also be classified into Injection Moulded and Flexible magnets. Injection molded
204 magnets are a composite of various types of resin and magnetic powders, allowing parts of complex shapes to
205

206 be manufactured by injection molding. The physical and magnetic properties of the product depend on the raw
207 materials, but are generally lower in magnetic strength and resemble plastics in their physical properties.

208 **20 iii. Shape & Configuration**

209 Permanent magnets can be made into any shape imaginable. They can be made into round bars, rectangles,
210 horseshoes, donuts, rings, disks and other custom shapes. While the shape of the magnet is important aesthetically
211 and sometimes for experimentation, how the magnet is magnetized is equally important. For example: A ring
212 magnet can be magnetized S on the inside and N on the outside, or N on one edge and S on the other, or N on
213 the top side and S on the bottom. Depending on the end usage, the shape and configuration vary.

214 **21 iv. Demagnetization**

215 Permanent magnets can be demagnetized in the following ways: -Heat -Heating a magnet until it is red hot makes
216 it loose its magnetic properties. -Contact with another magnet -Stroking one magnet with another in a random
217 fashion, will demagnetize the magnet being stroked. -Hammering or jarring will loosen the magnet's atoms from
218 their magnetic attraction.

219 **22 v. Temporary Magnets**

220 Temporary magnets are those that simply act like permanent magnets when they are within a strong magnetic
221 field. Unlike permanent magnets however, they loose their magnetism when the field disappears. Paperclips, iron
222 nails and other similar items are examples of temporary magnets. Temporary magnets are used in telephones
223 and electric motors amongst other things.

224 **23 vi. Electromagnets**

225 Had it not been for electromagnets we would have been deprived of many luxuries and necessities in life including
226 computers, television and telephones. Electromagnets are extremely strong magnets. They are produced by
227 placing a metal core (usually an iron alloy) inside a coil of wire carrying an electric current. The electricity in
228 the current produces a magnetic field. The strength of the magnet is directly proportional to the strength of
229 the current and the number of coils of wire. Its polarity depends on the direction of flow of current. While the
230 current flows, the core behaves like a magnet. However, as soon as the current stops, the core is demagnetized.
231 vii. Superconductors These are the strongest magnets. They don't need a metal core at all, but are made of coils
232 of wire made from special metal alloys which become superconductors when cooled to very low temperatures.

233 **24 viii. Electromagn**

234 An electromagnet is a type of magnet in which the magnetic field is produced by the flow of electric current.
235 The magnetic field disappears when the current is turned off. Electromagnets are widely used as components of
236 other electrical devices, such as motors , generators, relays, loudspeakers, hard disks, MRI machines, scientific
237 instruments, and magnetic separation equipment, as well as being employed as industrial lifting electromagnets
238 for picking up and moving heavy iron objects like scrap iron.

239 A simple electromagnet consisting of a coil of insulated wire wrapped around an iron core. The strength of
240 magnetic field generated is proportional to the amount of current. Figure 6.7 : Faraday's Thumb Rule Current
241 (I) through a wire produces a magnetic field (B). The field is oriented according to the right-hand rule. An
242 electric current flowing in a wire creates a magnetic field around the wire (see drawing below). To concentrate
243 the magnetic field, in an electromagnet the wire is wound into a coil with many turns of wire lying side by side.
244 The magnetic field of all the turns of wire passes through the center of the coil, creating a strong magnetic field
245 there. A coil forming the shape of a straight tube (a helix) is called a solenoid. Much stronger magnetic fields
246 can be produced if a "core" of ferromagnetic material, such as soft iron, is placed inside the coil. Magnetic field
247 produced by a solenoid (coil of wire). This drawing shows a cross section through the center of the coil. The
248 crosses are wires in which current is moving into the page; the dots are wires in which current is moving up out
249 of the page.

250 The direction of the magnetic field through a coil of wire can be found from a form of the right-hand rule. If
251 the fingers of the right hand are curled around the coil in the direction of current flow (conventional current, flow
252 of positive charge) through the windings, the thumb points in the direction of the field inside the coil. The side
253 of the magnet that the field lines emerge from is defined to be the north pole.

254 The main advantage of an electromagnet over a permanent magnet is that the magnetic field can be rapidly
255 manipulated over a wide range by controlling the amount of electric current. However, a continuous supply of
256 electrical energy is required to maintain the field.

257 **25 How to Make an Electromagnet**

258 To make a simple electromagnet, you can wrap 50 or 100 turns of thin insulated copper wire along the length of
259 an iron nail, forming a neat coil of wire tight along and around the nail. (Leave about 9 inches of wire free at
260 each end of the coil to attach to the power source). 1. Wrap the insulated wire around the nail, moving down

261 the nail as you go. 2. Fix the coil of wire in place with some sticky tape. 3. Clean off the insulation at the ends
262 of the extra wire, for about 1 inch, exposing the shiny metal inside. 4. Bend the ends into loops and connect to
263 a LOW VOLTAGE direct-current power supply, such as a model train transformer or a D-cell battery pack.

264 **26 c) DC Motor**

265 A DC motor is a mechanically the principle commutated electric motor powered from direct current (DC). The
266 stator is stationary in space by definition and therefore its current. The current in the rotor is switched by the
267 commutator to also be stationary in space. This is how the relative angle between the stator and rotor magnetic
268 flux is maintained near 90 degrees, which generates the maximum torque. DC motors have a rotating armature
269 winding (winding in which a voltage is induced) but non-rotating armature magnetic field and a static field
270 winding (winding that produce the main magnetic flux) or permanent magnet. Different connections of the field
271 and armature winding provide different inherent speed/torque regulation characteristics. The speed of a DC
272 motor can be controlled by changing the voltage applied to the armature or by changing the field current. The
273 introduction of variable resistance in the armature circuit or field circuit allowed speed control. The introduction
274 of DC motors to run machinery eliminated the need for local steam or internal combustion engines, and line shaft
275 drive systems. i. Brush A brushed DC electric motor generating torque from DC power supply by using internal
276 mechanical commutation, space stationary permanent magnets form the stator field. Torque is produced by the
277 principle of Lorentz force, which states that any current-carrying conductor placed within an external magnetic
278 field experiences a force known as Lorentz The actual (Lorentz) force (and also torque since torque is $F \times l$ where
279 l is rotor radius) is a function for rotor angle and so the green arrow/vector actually changes length/magnitude
280 force. with angle known as torque ripple) Since this is a single phase two pole motor the commutator consists of
281 a split ring, so that the current reverses each half turn (180 degrees).

282 The brushed DC electric motor generates torque directly from DC power supplied to the motor by using
283 internal commutation, stationary magnets (permanent or electromagnets), and rotating electrical magnets.

284 ii.

285 **27 Brushless**

286 Typical brushless DC motors use a rotating permanent magnet in the rotor, and stationary electrical current/coil
287 magnets on the motor for the rotor, but the symmetrical opposite is also possible. A motor controller converts DC
288 to AC. This design is simpler than that of brushed motors because it eliminates the complication of transferring
289 power from outside the motor to the spinning rotor. Advantages of brushless motors include long life span, little
290 or no maintenance, and high efficiency. Disadvantages include high initial cost, and more complicated motor
291 speed controllers. Some such brushless motors are sometimes referred to as "synchronous motors" although they
292 have no external power supply to be synchronized with, as would be the case with normal AC synchronous motors.
293 Other types of DC motors require no commutation. Homopolar motor -A homopolar motor has a magnetic field
294 along the axis of rotation and an electric current that at some point is not parallel to the magnetic field. The
295 name homopolar refers to the absence of polarity change.

296 Homopolar motors necessarily have a singleturn coil, which limits them to very low voltages. This has restricted
297 the practical application of this type of motor. Ball bearing motor -A ball bearing motor is an unusual electric
298 motor that consists of two ball bearing-type bearings, with the inner races mounted on a common conductive
299 shaft, and the outer races connected to a high current, low voltage power supply. current is common to both
300 the stator and rotor yielding I^2 (current) squared behavior. A series motor has very high starting torque and is
301 commonly used for starting high inertia loads, such as trains, elevators or hoists. This speed/torque characteristic
302 is useful in applications such as dragline excavators, where the digging tool moves rapidly when unloaded but
303 slowly when carrying a heavy load.

304 With no mechanical load on the motor, the current is low, the counter-EMF produced by the field winding
305 is weak, and so the armature must turn faster to produce sufficient counter-EMF to balance the supply voltage.
306 The motor can be damaged This is called a runaway condition. Series motors called "universal motors" can be
307 used on alternating current. Since the armature voltage and the field direction reverse at (substantially) the
308 same time, torque continues to be produced in the same direction.

309 **28 vi. Shunt Connection**

310 A shunt DC motor connects the armature and field windings in parallel or shunt with a common D.C. power
311 source. This type of motor has good speed regulation even as the load varies, but does not have the starting
312 torque of a series DC motor.

313 **29 vii. Compound Connection**

314 A compound DC motor connects the armature and fields windings in a shunt and a series combination to give it
315 characteristics of both a shunt and a series DC motor. This motor is used when both a high starting torque and
316 good speed regulation is needed. The motor can be connected in two arrangements: cumulatively or differentially.
317 Cumulative compound motors connect the series field to aid the shunt field, which provides higher starting torque
318 but less speed regulation. Graph derived from the above analysis:

329 .1 ? Mumbai -Delhi

330 A maglev line project was presented to the then Indian railway minister (Mamta Banerjee) by an American
331 company. A line was proposed to serve between the cities of Mumbai and Delhi, the Prime Minister Manmohan
332 Singh said that if the line project is successful the Indian government would build lines between other cities and
333 also between Mumbai Central and Chhatrapati Shivaji International Airport.

334 ? Mumbai -Nagpur The Maharashtra has also approved a feasibility study for a maglev train between Mumbai
335 (the commercial capital of India as well as the State government capital) and Nagpur (the second State capital)
336 about 1,000 km (620 mi) away. It plans to connect the regions of Mumbai and Pune with Nagpur via less
337 developed hinterland (via Ahmednagar, Beed, Latur, Nanded and Yavatmal).

338 ? Chennai -Bangalore -Mysore Large and Medium Scale Industries Minister of Karnataka Mr. Muruges
339 Nirani, a detailed report will be prepared and submitted by December 2012 and the project is expected to cost
340 \$26 million per kilometer of railway track. The speed of Maglev will be 350 kmph and will take 30 mins from
341 Chennai to Mysore via Bangalore.

342 .2 Conclusion

343 ? We were able to successfully demonstrate with our model the feasibility of Levitation as a "Powerful Source"
344 to propel vehicles ? Dimension of the track and vehicle should be accurate in order to get better results. ? The
345 train is best levitated in center position.
