7 Abstract

Every organisation that produces product evaluates their performance at certain intervals to 8 keep the pace with the market. Forecasts are evaluated to improve models to achieve better 9 policy and planning outcomes. The purpose of this study is to observe whether the forecast 10 errors are within the reasonable limit of expectations or whether these errors are irrationally 11 large and require an improvement in the statistical models and process of producing these 12 forecasts. Statistical time series modelling techniques like â??" Moving Average, Simple 13 Exponential Smoothing and Least Square methods are used for the study and their 14 performance evaluated in terms of Mean Average Deviation (MAD), Mean Squared Error 15 (MSE). 16

17

6

18 Index terms— moving average method, simple exponential smoothing method, least square method, mean 19 average deviation, mean squared error (MSE).

20 1 Introduction

odern production activities are becoming more complex technologically, the basic inputs are becoming expensive 21 and there are lot of restrictions on them. The planning of the production activities is, therefore, essential to put 22 the resources for best use. Planning is a fundamental activity of management. Forecasting forms the basis of 23 24 planning and it enables the organisation to respond more quickly and accurately to market changes. It plays 25 a crucial role in the development of plans for the future. It is essential for the organisations to know for what level of activities one is planning before investments in inputs i.e. men, machines and materials. It uses many 26 27 statistical techniques. Therefore, it is also called as Statistical Analysis. It refers to a systematic analysis of past 28 and present circumstances. It is essentially a technique of anticipation. Before making an investment decision, questions may arise like: 29

- 30 ? What should be the size of the order and safety stock?
- ? What should be the capital cost required for the work?
- 32 ? What should be the capacity of the plant?
- 33 ? How much labour is required?

The answers to the above questions depend upon the forecast for the future level of operations. The success of a business greatly depends upon the efficient forecasting and preparing for future events. It should be no surprise that forecasts are not always accurate -they are essentially about predicting the future with incomplete information. Nevertheless, forecast inaccuracies, particularly consistent underestimation of revenues and budget surpluses generally draws intense criticism. Forecast accuracy has been a matter of concern and subject of review. In general, the reasons for inaccuracies may fall into the following categories:

40 ? Technical issues, such as data accuracy, forecasting methodology, process and agency structures.

41 ? Effects of fiscal objectives.

? The economic cycle. Forecasting agencies generally review and improve data and models on an ongoingbasis, and issues identified in major reviews are generally marginal.

44 **2** II.

45 **3** Aims and Objectives

The main emphasis of this work is to compare the various forecasting techniques prevalent in the industries based on the data obtained from a juice producing factory. In this manuscript an attempt has been made to forecast juice production by using the Moving Average Method, Simple Exponential Smoothing and Least Square Method. The aim is to evaluate the performances in terms of

50 4 Methodology

This study was carried out on the basis of juice production data collected for the period 2000 to 2011 as shown in 51 the table 1. When demand for a product is neither growing nor declining rapidly and if it does not have seasonal 52 characteristics, a moving average can be useful in removing the random fluctuations for forecasting. Although 53 moving averages are frequently centered, it is more convenient to use past data to predict the following period 54 directly. Although it is important to select the best period for the moving average, there are several conflicting 55 effects of different period lengths. The different moving averages produce different forecasts. The greater the 56 number of periods in the moving average, the greater the smoothing effect. If the underlying trend of the past 57 data is thought to be fairly constant with substantial randomness, then a greater number of periods should be 58 chosen. The formula for a simple moving average is F t = (A t-1 + A t-2 + A t-3 + A t-n) n(1)59

Where , F t = Forecast for the coming period, n = Number of period to be averaged n and A t-1 , A t-2 , A t-3 = Actual occurrences in the in the past period, two periods ago, three periods ago and so on respectively.

Equal weighting is given to each of the values used in the moving average calculation, whereas it is reasonable to suppose that the most recent data is more relevant to current conditions. An n period moving average requires the storage of (n-1) value to which is added the latest observation. This may not seem much of a limitation when only a few items are considered. The moving average calculation takes no account of data outside the period of average, so full use is not made of all the data available. The use of the unadjusted moving average as a forecast

67 can cause misleading results when there is an underlying seasonal variation.

⁶⁸ 5 b) Simple Exponential Smoothing Method

⁶⁹ In the previous forecasting method, the major drawback is the need to continually carry a large amount of ⁷⁰ historical data. As each new piece of data is added in these methods, the oldest observation is dropped, and the ⁷¹ new forecast is calculated. The reason this is called exponential smoothing is that each increment in the past ⁷² is decreased by **??1**-?). This method provides short term forecasts. The simplest formula is New forecast = Old

73 forecast + ? (Latest Observation -Old Forecast)

Or more mathematically, F t = F t-1 + ? (A t-1 -F t-1).

(2) Where, Ft = The exponentially smoothed forecast for period t, F t-1 = The exponentially smoothed forecast made for the prior period, A t-1 = The actual demand in the prior period, ? = The desired response rate, or smoothing constant.

The value of smoothing constants ? varies from 0 to 1. The higher value of ? (i.e. the nearer to 1), the more 78 sensitive the forecast becomes to current conditions, whereas the lower the value, the more stable the forecast 79 will be, i.e. it will react less sensitively to current conditions. Here the value of alpha is taken as 0.3.Greater 80 weight is given to more recent data. All past data are incorporated there is no cut-off point as with moving 81 averages. Less data needs to be stored than with the longer period moving averages. Like moving averages it 82 is an adaptive forecasting system. That is, it adapts continually as new data becomes available and so it is 83 frequently incorporated as an integral part of stock control and production control systems. To cope with various 84 problems (trend, seasonal factors, etc) the basic model needs to be modified. Whatever form of exponential 85 smoothing is adopted, changes to the model to suit changing conditions can simply be made by altering the value 86 of ?. The selection of the smoothing constant ? is done through trial-error by the researcher/analyst. It is done 87 by testing several values of ? (within the range 0 to 1) and selecting one which gives a forecast with the least 88 error (one can take standard error). It has been found that values in the range 0.1 to 0.3 provide a good starting 89 90 point.

91 6 c) Least Squares Method

92 This is the mathematical method of obtaining the line of best fit between the dependent variable and an 93 independent variable. In this, the sum of the square of the deviations of the various points from the line of 94 best fit is minimum or least. (5)

These two equations are called normal equations. It is useful for long-term forecasting of major occurrences and aggregate planning. The major restriction in using linear forecasting is that past data and future projections are assumed to fall about a straight line. Although, this does limits its application.

⁹⁸ 7 d) Evaluating the Forecast Accuracy

⁹⁹ There are many ways to measure forecast accuracy. Some of these measures are the mean absolute forecast ¹⁰⁰ error, called the MAD (Mean Absolute Deviation), the mean absolute percentage error (MAPE) and the mean

square error (MSE). This error estimate helps in monitoring erratic demand observations. In addition, they 101 also help to determine when the forecasting method is no longer tracking actual demand and it need to be 102 reset. For this tracking signals are used to indicate any positive or negative bias in the forecast. The mean 103 absolute deviation (MAD) is also important because of its simplicity and usefulness in obtaining tracking signals. 104 MAD is the average error in the forecasts, using absolute values. It is valuable because MAD, like the standard 105 deviation, measures the dispersion of some observed value from some expected value. The only difference is that 106 like standard deviation, the errors are not squared. Standard error a square root of a function, it is often more 107 convenient to use the function itself. This is called the mean square error (MSE) or variance. The mathematical 108 formulas may be used while evaluating data are 109

¹¹⁰ 8 result analysis

¹¹¹ In this study, we used the data for juice production for the period 2000-01 to 2010-2011. All the three methods ¹¹² are applied one by one and their performance evaluated in terms of MAD, MAPE and MSE.

¹¹³ 9 a) Moving Average Method

114 10 Discussion

Initially time series plot (Figure 1) was created to determine the trends in the juice production from 2003 to 115 2011, the graph shows an increasing trend in juice production during the study period and hence showed that the 116 series was not stationary. It is very clear from the graph that the trend line of Least Square Average method flow 117 on the actual trend line of juice production. The trend line of Simple exponential method is far away from the 118 actual trend line. And finally the performance of the various methods evaluated on the basis of MAPE, MAD 119 and MSE which is shown in the table 6. By comparing the performance of the methods, it was found that Least 120 Square method have least value of MAPE (15.74%), MAD (0.25) and MSE (0.09) and hence the results produced 121 122 by the least square method have less error and more accurate than the other method.

123 **11 VI.**

124 12 Conclusion

Forecasting of juice production done by using statistical methods, (Moving Average method, Simple Exponential Method and Least Square Method). Statistical methods are chosen because for their rich historic data and ease of their use. Finally, their performance evaluated by comparing the MAPE, MAD and MSE obtained from the different methods. The results show that least Square method is more accurate than the other methods.

The forecasting technique may be different for different industries. It depends upon the variable factors like place, manpower skill, equipment capacity, raw material availability, inventory characteristics and management policies etc. Hence this work may be extended to other industries.
