Abstract

The generation of electricity and consumption of energy in general, result adverse effects on the environment. Barapukuria is the only natural coalmine reserve in Bangladesh that is currently in operation. Barapukuria thermal power plant produces electricity from the reserved coal. The coal available in Bangladesh is of very high quality, with low ash content and high calorific value. Coal quality plays a great role in environmental impact as well as gaseous emissions. Source of water is the major problem for the Barapukuria thermal power plant and there is a poor disposal system of the waste water. By collecting the secondary data from the authority of the Barapukuria thermal power plant, this study was accomplished at Barapukuria thermal power plant to evaluate the pollutant (SO₂) emission rate and its impact on human health due to air pollution. In this study attempts were made to find out the major environmental impacts to Barapukuria thermal power plant and finally showed the possible recommendations to reduce the impacts.

Index terms— emission; health impact; environmental pollution; thermal power plant.

1 Introduction

thermal power station is a power plant in which the prime mover is steam driven. Water is heated, turns into steam and spins a steam turbine which drives an electrical generator. After it passes through the turbine, the steam is condensed in a condenser and recycled to where it was heated; this is known as a Rankine cycle [1]. Barapukuria power plant is a power station which follows the Rankine cycle. Barapukuria is the only natural coalmine reserve in Bangladesh that is in currently operation. The overall capacity of Barapukuria Thermal Power Plant is 250MW. Total electricity generation is extracted into two units as 2x125MW. In order to alleviate the electricity crisis in Bangladesh, Barapukuria Coal and Power project is a blessing indeed [2].

Besides the blessing indeed property Barapukuria power plant has some adverse effect also. One of the major effects of the power station is the exhaust emission. Due to continuous & long lasting emission of SO_x & NO_x, which are the principal pollutants coal based plants.. It is also worth to note that very high amount of carbon dioxide (CO₂) emission (0.9-0.95kg/kWh) from thermal power plants contribute to global warming leading to climate change [3].

Also Thermal Power Plants have been found to affect Environmental segments of the surrounding region very badly. Environmental deterioration is attributed to emission of large amount of SO_x, NO_x & SPM which disperse over 25kms radius and cause respiratory and related ailments to human beings and animal kingdom. The SPM also includes RSPM (respirable suspended particulate matters) and both types of fine particles normally spread over 25kms from the Thermal Power station.

Alam et al. [4] in their study gives emphasis on the evaluation of possible environmental impacts for Barapukuria thermal power plant and coal mine. In his work an attempt was taken to conduct environmental impact assessment of Barapukuria thermal power. Tamim et al. [5] shows the analysis of fly ash of Barapukuria thermal power plant. Fly ash is one of the common residues produced from combustion of coal. But the study

was not enough to recommend the possible measurement to reduce the adverse impact of Barapukuria Power Plant. Now the aim is that, to find out the possible environmental impacts by studying the data from water treatment plant, coal handling unit, ash handling unit and I & C department of Barapukuria thermal power plant and recommending the possible way to minimize the impacts.

II.

3 Methodology

The study was based on field observations, sample collections and data collection. Coal, soil and drain water samples were collected from the study area for sampling. Coal sample and soil data are collected from the authority of Barapukuria thermal power plant.

Overall thesis work was completed by following steps:

Data Collection: The thesis covers both secondary and primary data. Here secondary and primary data sources are used to estimate the emissions and their effects from Barapukuria thermal power plant.

Secondary Data: Secondary data were collected from the authority of Barapukuria thermal power plant, sequentially from the water treatment plant, I&C department, coal & ash handling unit.

Primary Data: Primary data were collected from the analysis of several thesis work based on Barapukuria thermal power plant.

Drain water sample was collected from the Barapukuria thermal power plant and data of drained water collected from the chemistry department to find Exhaust gas emission data was collected from the I&C department of the Barapukuria thermal power plant. Fly ash quantities was calculated from the data given by the authority.

4 Data Collection and Analysis

As mentioned in the methodology that the data is collected from the different sources.

Survey to the inhabitants: A survey was directed to the surrounding area within about 5km from the power plant. A conversation was made among 210 people of different profession nearby the plant area to investigate the impact on their health. They informed about their health condition (suffered by the Barapukuria power plant). The survey was based on several questions about asthma, allergy, skin diseases, and other respiratory problems on their health impact. Result of the survey given in table (1). The above Table 1 reveals that 14% of the inhabitants suffer from allergy, asthma, skin diseases and other respiratory problems and the 58% of the inhabitants were undecided and rest of the 38% were disagreed about the effect of exhaust emission from the Barapukuria thermal power plant.

Conversation was also made with the local doctors about the patient condition around the power plant area. They informed that the skin diseases and the respiratory problems have been increased since when the Barapukuria power plant started operation in 2006. It is clear from the analysis that the Mn concentration was found in the range 0.19 to 0.26 mg/L. The ph was found slightly acidic (7.2 to 7.4). Bacteria is within WHO ranges. The concentration of bacteria was found from 7.5. It is also found that S0 4 2concentration is 2.4 mg/l in gut side boundary drain water and 3.1 mg/l in outside boundary water, which is within the WHO range .NO 3 is slightly varied from the standard range and the concentration of Fe3 was found within the WHO range.

V.

5 Coal Analysis

Coal, the most important fossil fuel remained essential in achieving a diverse, balance and secure energy mix. Barapukuria Coal field has been operating officially since 2004, with a coal reserve of 390 Million Tones. The yearly production is 1 million tones, out of which 65% is supplied to the Barapukuria Coal fired Thermal Power Plant, the only operating thermal power plant of Bangladesh, with a capacity of 250MW [6]. Fly ash disposal is carried out by two techniques, namely dry disposal scheme and Wet disposal scheme. In dry disposal, the produced fly ash is transported from site by various methods (truck, conveyor belt etc.) and disposed into a dry embankment. In wet disposal, the fly ash is mixed with water to form a slurry, which is transported by pipes to be disposed off in a confinement called the 'ash pond' [7]. All the reading are taken away from the emission point of power plant, this show that emission is somehow more than allowable limit. When the power plant which are in construction phase when they start their operation then this limit is easily exceeded. So we should take care of all such factors as well as take necessary preventive action to control this emission level .

VI. Impact on water: The water requirement for Barapukuria thermal power plant is 60ton/hr for each unit. Among these water 30 ton/hr is drained and rest of water is recycling. Ash pond decant contains harmful heavy metals like B, As, Hg which have a tendency to leach out over a period of time. Due to this the ground water gets polluted and becomes unsuitable for domestic use. 9m³ /h of industrial waste water is discharged directly into the Tilai River without waste water cleaning. a) The drained water which is directly disposed to the Tilai river without cleaning waste water should be cleaned before disposing. b) There is not any process of reusing the ash, directly thrown in the nearest ash pond. Fly ash can be used in different construction purposes. From the study of this thesis shows that the analyzed fly ash are of useful component for recovery of alumina, opencast mine filling, road reclamation, cement and concrete production, waste water treatment and various agricultural

applications. c) Flue Gas De-sulphurization (FGD) process can be applied to remove sulphur from the flue gas
More source of water can be thought not only by using the ground water VIII.

6 Summerisation of Impacts on Environment

7 Conclusion

The analysis showed that the emission of SO_x, NO_x and particulates matter is in allowable range but this may cause adverse effect to the environment of the surrounding region. ? Total emissions from the Barapukuria thermal power plant is 1.1ton/hr. ? The high amount of CO₂ emission from thermal power plants before 2009 was 756,020 tons, that make the Barapukuria thermal power plant a red marked power plant in this zone ? Problem associated with ground water is the main challenge of Barapukuria Thermal Power Plant. ? There found poor productivity of cultivating crops due to the lack of water source. ? Upper surface of land become more alkaline due to components of fly ash. ? A significant amount of inhabitants (14%) suffered by the impacts of Barapukuria thermal power plant. ? 47.3 % of inhabitants ensured about less production of their crops, ash in the air, and leaf damage due to fly ash or flue gas.
